49.3.1 UART Baud Rate Registers: High (UARTx_BDH)

This register, along with the BDL register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting (SBR[12:0]), first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written.

BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 0h offset

Bit	7	6	5	4	3	2	1	0
Read	LBKDIE	RXEDGIE	0	SBR				
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_BDH field descriptions

Field	Description
7 LBKDIE	LIN Break Detect Interrupt Enable Enables the LIN break detect flag, LBKDIF, to generate interrupt requests based on the state of LBKDDMAS. 0 LBKDIF interrupt requests disabled. 1 LBKDIF interrupt requests enabled.
6 RXEDGIE	RxD Input Active Edge Interrupt Enable Enables the receive input active edge, RXEDGIF, to generate interrupt requests. 0 Hardware interrupts from RXEDGIF disabled using polling. 1 RXEDGIF interrupt request enabled.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–0 SBR	UART Baud Rate Bits The baud rate for the UART is determined by the 13 SBR fields. See Baud rate generation for details. **NOTE:** • The baud rate generator is disabled until C2[TE] or C2[RE] is set for the first time after reset.The baud rate generator is disabled when SBR = 0. • Writing to BDH has no effect without writing to BDL, because writing to BDH puts the data in a temporary location until BDL is written.

49.3.2 UART Baud Rate Registers: Low (UARTx_BDL)

This register, along with the BDH register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting, SBR[12:0], first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written. BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 1h offset

Bit	7	6	5	4	3	2	1	0
Read / Write	SBR							
Reset	0	0	0	0	0	1	0	0

UARTx_BDL field descriptions

Field	Description
7–0 SBR	UART Baud Rate Bits The baud rate for the UART is determined by the 13 SBR fields. See Baud rate generation for details. **NOTE:** • The baud rate generator is disabled until C2[TE] or C2[RE] is set for the first time after reset.The baud rate generator is disabled when SBR = 0. • Writing to BDH has no effect without writing to BDL, because writing to BDH puts the data in a temporary location until BDL is written. • When the 1/32 narrow pulse width is selected for infrared (IrDA), the baud rate fields must be even, the least significant bit is 0. See MODEM register for more details.

49.3.3 UART Control Register 1 (UARTx_C1)

This read/write register controls various optional features of the UART system.

Address: Base address + 2h offset

Bit	7	6	5	4	3	2	1	0
Read / Write	LOOPS	Reserved	RSRC	M	WAKE	ILT	PE	PT
Reset	0	0	0	0	0	0	0	0

UARTx_C1 field descriptions

Field	Description
7 LOOPS	Loop Mode Select When LOOPS is set, the RxD pin is disconnected from the UART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.

Table continues on the next page...

UARTx_C1 field descriptions (continued)

Field	Description
	0 Normal operation. 1 Loop mode where transmitter output is internally connected to receiver input. The receiver input is determined by RSRC.
6 Reserved	Reserved. This field is reserved.
5 RSRC	Receiver Source Select This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input. 0 Selects internal loop back mode. The receiver input is internally connected to transmitter output. 1 Single wire UART mode where the receiver input is connected to the transmit pin input signal.
4 M	9-bit or 8-bit Mode Select This field must be set when C7816[ISO_7816E] is set/enabled. 0 Normal—start + 8 data bits (MSB/LSB first as determined by MSBF) + stop. 1 Use—start + 9 data bits (MSB/LSB first as determined by MSBF) + stop.
3 WAKE	Receiver Wakeup Method Select Determines which condition wakes the UART: • Address mark in the most significant bit position of a received data character, or • An idle condition on the receive pin input signal. 0 Idle line wakeup. 1 Address mark wakeup.
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE:** • In case the UART is programmed with ILT = 1, a logic of 1'b0 is automatically shifted after a received stop bit, therefore resetting the idle count. • In case the UART is programmed for IDLE line wakeup (RWU = 1 and WAKE = 0), ILT has no effect on when the receiver starts counting logic 1s as idle character bits. In idle line wakeup, an idle character is recognized at anytime the receiver sees 10, 11, or 12 1s depending on the M, PE, and C4[M10] fields. 0 Idle character bit count starts after start bit. 1 Idle character bit count starts after stop bit.
1 PE	Parity Enable Enables the parity function. When parity is enabled, parity function inserts a parity bit in the bit position immediately preceding the stop bit. This field must be set when C7816[ISO_7816E] is set/enabled. 0 Parity function disabled. 1 Parity function enabled.
0 PT	Parity Type

Table continues on the next page...

UARTx_C1 field descriptions (continued)

Field	Description
	Determines whether the UART generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit. This field must be cleared when C7816[ISO_7816E] is set/enabled. 0 Even parity. 1 Odd parity.

49.3.4 UART Control Register 2 (UARTx_C2)

This register can be read or written at any time.

Address: Base address + 3h offset

Bit	7	6	5	4	3	2	1	0
Read Write	TIE	TCIE	RIE	ILIE	TE	RE	RWU	SBK
Reset	0	0	0	0	0	0	0	0

UARTx_C2 field descriptions

Field	Description
7 TIE	Transmitter Interrupt or DMA Transfer Enable. Enables S1[TDRE] to generate interrupt requests or DMA transfer requests, based on the state of C5[TDMAS]. **NOTE:** If C2[TIE] and C5[TDMAS] are both set, then TCIE must be cleared, and D[D] must not be written unless servicing a DMA request. 0 TDRE interrupt and DMA transfer requests disabled. 1 TDRE interrupt or DMA transfer requests enabled.
6 TCIE	Transmission Complete Interrupt Enable Enables the transmission complete flag, S1[TC], to generate interrupt requests . 0 TC interrupt requests disabled. 1 TC interrupt requests enabled.
5 RIE	Receiver Full Interrupt or DMA Transfer Enable Enables S1[RDRF] to generate interrupt requests or DMA transfer requests, based on the state of C5[RDMAS]. 0 RDRF interrupt and DMA transfer requests disabled. 1 RDRF interrupt or DMA transfer requests enabled.
4 ILIE	Idle Line Interrupt Enable Enables the idle line flag, S1[IDLE], to generate interrupt requests

Table continues on the next page...

UARTx_C2 field descriptions (continued)

Field	Description
	0 IDLE interrupt requests disabled. 1 IDLE interrupt requests enabled.
3 TE	Transmitter Enable Enables the UART transmitter. TE can be used to queue an idle preamble by clearing and then setting TE. When C7816[ISO_7816E] is set/enabled and C7816[TTYPE] = 1, this field is automatically cleared after the requested block has been transmitted. This condition is detected when TL7816[TLEN] = 0 and four additional characters are transmitted. 0 Transmitter off. 1 Transmitter on.
2 RE	Receiver Enable Enables the UART receiver. 0 Receiver off. 1 Receiver on.
1 RWU	Receiver Wakeup Control This field can be set to place the UART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when C1[WAKE] is clear or an address match when C1[WAKE] is set. This field must be cleared when C7816[ISO_7816E] is set. **NOTE:** RWU must be set only with C1[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by S2[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the UART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to reasserted. 0 Normal operation. 1 RWU enables the wakeup function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU.
0 SBK	Send Break Toggling SBK sends one break character from the following: See Transmitting break characters for the number of logic 0s for the different configurations. Toggling implies clearing the SBK field before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send complete break characters (10, 11, or 12 bits, or 13 or 14 bits). Ensure that C2[TE] is asserted atleast 1 clock before assertion of this bit. • 10, 11, or 12 logic 0s if S2[BRK13] is cleared • 13 or 14 logic 0s if S2[BRK13] is set. This field must be cleared when C7816[ISO_7816E] is set. 0 Normal transmitter operation. 1 Queue break characters to be sent.

49.3.5 UART Status Register 1 (UARTx_S1)

The S1 register provides inputs to the MCU for generation of UART interrupts or DMA requests. This register can also be polled by the MCU to check the status of its fields. To clear a flag, the status register should be read followed by a read or write to D register, depending on the interrupt flag type. Other instructions can be executed between the two steps as long the handling of I/O is not compromised, but the order of operations is important for flag clearing. When a flag is configured to trigger a DMA request, assertion of the associated DMA done signal from the DMA controller clears the flag.

NOTE

- If the condition that results in the assertion of the flag, interrupt, or DMA request is not resolved prior to clearing the flag, the flag, and interrupt/DMA request, reasserts. For example, if the DMA or interrupt service routine fails to write sufficient data to the transmit buffer to raise it above the watermark level, the flag reasserts and generates another interrupt or DMA request.
- Reading an empty data register to clear one of the flags of the S1 register causes the FIFO pointers to become misaligned. A receive FIFO flush reinitializes the pointers. A better way to prevent this situation is to always leave one byte in FIFO and this byte will be read eventually in clearing the flag bit.

Address: Base address + 4h offset

Bit	7	6	5	4	3	2	1	0
Read	TDRE	TC	RDRF	IDLE	OR	NF	FE	PF
Write								
Reset	1	1	0	0	0	0	0	0

UARTx_S1 field descriptions

Field	Description
7 TDRE	Transmit Data Register Empty Flag TDRE will set when the number of datawords in the transmit buffer (D and C3[T8])is equal to or less than the number indicated by TWFIFO[TXWATER]. A character that is in the process of being transmitted is not included in the count. To clear TDRE, read S1 when TDRE is set and then write to the UART data register (D). For more efficient interrupt servicing, all data except the final value to be written to the buffer must be written to D/C3[T8]. Then S1 can be read before writing the final data value, resulting in the clearing of the TRDE flag. This is more efficient because the TDRE reasserts until the watermark has been exceeded. So, attempting to clear the TDRE with every write will be ineffective until sufficient data has been written.

Table continues on the next page...

UARTx_S1 field descriptions (continued)

Field	Description
	0 The amount of data in the transmit buffer is greater than the value indicated by TWFIFO[TXWATER]. 1 The amount of data in the transmit buffer is less than or equal to the value indicated by TWFIFO[TXWATER] at some point in time since the flag has been cleared.
6 TC	Transmit Complete Flag TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by reading S1 with TC set and then doing one of the following: When C7816[ISO_7816E] is set/enabled, this field is set after any NACK signal has been received, but prior to any corresponding guard times expiring.When C6[EN709] is set/enabled, this flag is not set on transmit packet completion. • Writing to D to transmit new data. • Queuing a preamble by clearing and then setting C2[TE]. • Queuing a break character by writing 1 to SBK in C2. 0 Transmitter active (sending data, a preamble, or a break). 1 Transmitter idle (transmission activity complete).
5 RDRF	Receive Data Register Full Flag RDRF is set when the number of datawords in the receive buffer is equal to or more than the number indicated by RWFIFO[RXWATER]. A dataword that is in the process of being received is not included in the count. To clear RDRF, read S1 when RDRF is set and then read D. For more efficient interrupt and DMA operation, read all data except the final value from the buffer, using D/C3[T8]/ED. Then read S1 and the final data value, resulting in the clearing of the RDRF flag. Even if RDRF is set, data will continue to be received until an overrun condition occurs.RDRF is prevented from setting while S2[LBKDE] is set. Additionally, when S2[LBKDE] is set, the received datawords are stored in the receive buffer but over-write each other. 0 The number of datawords in the receive buffer is less than the number indicated by RXWATER. 1 The number of datawords in the receive buffer is equal to or greater than the number indicated by RXWATER at some point in time since this flag was last cleared.
4 IDLE	Idle Line Flag After the IDLE flag is cleared, a frame must be received (although not necessarily stored in the data buffer, for example if C2[RWU] is set), or a LIN break character must set the S2[LBKDIF] flag before an idle condition can set the IDLE flag. To clear IDLE, read UART status S1 with IDLE set and then read D. IDLE is set when either of the following appear on the receiver input: • 10 consecutive logic 1s if C1[M] = 0 • 11 consecutive logic 1s if C1[M] = 1 and C4[M10] = 0 • 12 consecutive logic 1s if C1[M] = 1, C4[M10] = 1, and C1[PE] = 1 Idle detection is not supported when7816Eor EN709is set/enabled and hence this flag is ignored. **NOTE:** When RWU is set and WAKE is cleared, an idle line condition sets the IDLE flag if RWUID is set, else the IDLE flag does not become set. 0 Receiver input is either active now or has never become active since the IDLE flag was last cleared. 1 Receiver input has become idle or the flag has not been cleared since it last asserted.
3 OR	Receiver Overrun Flag OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the UART data registers is not affected. If the OR flag is set, no data is stored in the data buffer even if sufficient room exists. Additionally, while the OR flag is set, the RDRF and IDLE flags are blocked from asserting, that is, transition from an inactive to an active state. To clear OR, read

Table continues on the next page...

UARTx_S1 field descriptions (continued)

Field	Description
	S1 when OR is set and then read D. See functional description for more details regarding the operation of the OR bit.If LBKDE is enabled and a LIN Break is detected, the OR field asserts if S2[LBKDIF] is not cleared before the next data character is received. In 7816 mode, it is possible to configure a NACK to be returned by programing C7816[ONACK]. 0 No overrun has occurred since the last time the flag was cleared. 1 Overrun has occurred or the overrun flag has not been cleared since the last overrun occured.
2 NF	Noise Flag NF is set when the UART detects noise on the receiver input. NF does not become set in the case of an overrun or while the LIN break detect feature is enabled (S2[LBKDE] = 1). When NF is set, it indicates only that a dataword has been received with noise since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has noise or that there is only one dataword in the buffer that was received with noise unless the receive buffer has a depth of one. To clear NF, read S1 and then read D. When EN709 is set/enabled, noise flag is not set. 0 No noise detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1 then there may be data in the receiver buffer that was received with noise. 1 At least one dataword was received with noise detected since the last time the flag was cleared.
1 FE	Framing Error Flag FE is set when a logic 0 is accepted as the stop bit. FE does not set in the case of an overrun or while the LIN break detect feature is enabled (S2[LBKDE] = 1). FE inhibits further data reception until it is cleared. To clear FE, read S1 with FE set and then read D. The last data in the receive buffer represents the data that was received with the frame error enabled. Framing errors are not supported when 7816E is set/ enabled. However, if this flag is set, data is still not received in 7816 mode.Framing errors are not supported in 709 mode. 0 No framing error detected. 1 Framing error.
0 PF	Parity Error Flag PF is set when PE is set and the parity of the received data does not match its parity bit. The PF is not set in the case of an overrun condition. When PF is set, it indicates only that a dataword was received with parity error since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has a parity error or that there is only one dataword in the buffer that was received with a parity error, unless the receive buffer has a depth of one. To clear PF, read S1 and then read D., S2[LBKDE] is disabled,Within the receive buffer structure the received dataword is tagged if it is received with a parity error. This information is available by reading the ED register prior to reading the D register. 0 No parity error detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1, then there may be data in the receive buffer what was received with a parity error. 1 At least one dataword was received with a parity error since the last time this flag was cleared.

49.3.6 UART Status Register 2 (UARTx_S2)

The S2 register provides inputs to the MCU for generation of UART interrupts or DMA requests. Also, this register can be polled by the MCU to check the status of these bits. This register can be read or written at any time, with the exception of the MSBF and RXINV bits, which should be changed by the user only between transmit and receive packets.

Address: Base address + 5h offset

Bit	7	6	5	4	3	2	1	0
Read	LBKDIF	RXEDGIF	MSBF	RXINV	RWUID	BRK13	LBKDE	RAF
Write	w1c	w1c						
Reset	0	0	0	0	0	0	0	0

UARTx_S2 field descriptions

Field	Description
7 LBKDIF	LIN Break Detect Interrupt Flag LBKDIF is set when LBKDE is set and a LIN break character is detected on the receiver input. The LIN break characters are 11 consecutive logic 0s if C1[M] = 0 or 12 consecutive logic 0s if C1[M] = 1. LBKDIF is set after receiving the last LIN break character. LBKDIF is cleared by writing a 1 to it. 0 No LIN break character detected. 1 LIN break character detected.
6 RXEDGIF	RxD Pin Active Edge Interrupt Flag RXEDGIF is set when an active edge occurs on the RxD pin. The active edge is falling if RXINV = 0, and rising if RXINV=1. RXEDGIF is cleared by writing a 1 to it. See for additional details. RXEDGIF description **NOTE:** The active edge is detected only in two wire mode and on receiving data coming from the RxD pin. 0 No active edge on the receive pin has occurred. 1 An active edge on the receive pin has occurred.
5 MSBF	Most Significant Bit First Setting this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.In EN709 mode, this field affects the order of bits the same way as it does in normal mode. 0 LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0. 1 MSB (bit8, bit7 or bit6) is the first bit that is transmitted following the start bit, depending on the setting of C1[M] and C1[PE]. Further, the first bit received after the start bit is identified as bit8, bit7, or bit6, depending on the setting of C1[M] and C1[PE].
4 RXINV	Receive Data Inversion

Table continues on the next page...

UARTx_S2 field descriptions (continued)

Field	Description
	Setting this field reverses the polarity of the received data input. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity. A zero is represented by a short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity.This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.In EN709 mode, this bit affects the polarity of bits the same as it does in normal mode. **NOTE:** Setting RXINV inverts the RxD input for data bits, start and stop bits, break, and idle. When C7816[ISO7816E] is set/enabled, only the data bits and the parity bit are inverted. 0 Receive data is not inverted. 1 Receive data is inverted.
3 RWUID	Receive Wakeup Idle Detect When RWU is set and WAKE is cleared, this field controls whether the idle character that wakes the receiver sets S1[IDLE]. This field must be cleared when C7816[ISO7816E] is set/enabled. 0 S1[IDLE] is not set upon detection of an idle character. 1 S1[IDLE] is set upon detection of an idle character.
2 BRK13	Break Transmit Character Length Determines whether the transmit break character is 10, 11, or 12 bits long, or 13 or 14 bits long. See for the length of the break character for the different configurations. The detection of a framing error is not affected by this field. Transmitting break characters 0 Break character is 10, 11, or 12 bits long. 1 Break character is 13 or 14 bits long.
1 LBKDE	LIN Break Detection Enable Enables the LIN Break detection feature. While LBKDE is set, S1[RDRF], S1[NF], S1[FE], and S1[PF] are prevented from setting. When LBKDE is set, see . Overrun operationLBKDE must be cleared when C7816[ISO7816E] is set. 0 Break character detection is disabled. 1 Break character is detected at length of 11 bit times if C1[M] = 0 or 12 bits time if C1[M] = 1.
0 RAF	Receiver Active Flag RAF is set when the UART receiver detects a logic 0 during the RT1 time period of the start bit search. RAF is cleared when the receiver detects an idle character when C7816[ISO7816E] is cleared/disabled. When C7816[ISO7816E] is enabled, the RAF is cleared if the C7816[TTYPE] = 0 expires or the C7816[TTYPE] = 1 expires. **NOTE:** In case C7816[ISO7816E] is set and C7816[TTYPE] = 0, it is possible to configure the guard time to 12. However, if a NACK is required to be transmitted, the data transfer actually takes 13 ETU with the 13th ETU slot being a inactive buffer. Therefore, in this situation, the RAF may deassert one ETU prior to actually being inactive. 0 UART receiver idle/inactive waiting for a start bit. 1 UART receiver active, RxD input not idle.

49.3.7 UART Control Register 3 (UARTx_C3)

Writing R8 does not have any effect. TXDIR and TXINV can be changed only between transmit and receive packets.

Address: Base address + 6h offset

Bit	7	6	5	4	3	2	1	0
Read	R8	T8	TXDIR	TXINV	ORIE	NEIE	FEIE	PEIE
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_C3 field descriptions

Field	Description
7 R8	Received Bit 8 R8 is the ninth data bit received when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1. The R8 value corresponds to the current data value in the UARTx_D register. To read the 9th bit, read the value of UARTx_C3[R8], then read the UARTx_D register.
6 T8	Transmit Bit 8 T8 is the ninth data bit transmitted when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1. **NOTE:** If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten. To correctly transmit the 9th bit, write UARTx_C3[T8] to the desired value, then write the UARTx_D register with the remaining data.
5 TXDIR	Transmitter Pin Data Direction in Single-Wire mode Determines whether the TXD pin is used as an input or output in the single-wire mode of operation. This field is relevant only to the single wire mode. When C7816[ISO7816E] is set/enabled and C7816[TTYPE] = 1, this field is automatically cleared after the requested block is transmitted. This condition is detected when TL7816[TLEN] = 0 and 4 additional characters are transmitted. Additionally, if C7816[ISO7816E] is set/enabled and C7816[TTYPE] = 0 and a NACK is being transmitted, the hardware automatically overrides this field as needed. In this situation, TXDIR does not reflect the temporary state associated with the NACK. 0 TXD pin is an input in single wire mode. 1 TXD pin is an output in single wire mode.
4 TXINV	Transmit Data Inversion. Setting this field reverses the polarity of the transmitted data output. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity, and a zero is represented by short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity.This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode. **NOTE:** Setting TXINV inverts all transmitted values, including idle, break, start, and stop bits. In loop mode, if TXINV is set, the receiver gets the transmit inversion bit when RXINV is disabled. When C7816[ISO7816E] is set/enabled then only the transmitted data bits and parity bit are inverted.

Table continues on the next page...

UARTx_C3 field descriptions (continued)

Field	Description
	0 Transmit data is not inverted. 1 Transmit data is inverted.
3 ORIE	Overrun Error Interrupt Enable Enables the overrun error flag, S1[OR], to generate interrupt requests. 0 OR interrupts are disabled. 1 OR interrupt requests are enabled.
2 NEIE	Noise Error Interrupt Enable Enables the noise flag, S1[NF], to generate interrupt requests. 0 NF interrupt requests are disabled. 1 NF interrupt requests are enabled.
1 FEIE	Framing Error Interrupt Enable Enables the framing error flag, S1[FE], to generate interrupt requests. 0 FE interrupt requests are disabled. 1 FE interrupt requests are enabled.
0 PEIE	Parity Error Interrupt Enable Enables the parity error flag, S1[PF], to generate interrupt requests. 0 PF interrupt requests are disabled. 1 PF interrupt requests are enabled.

49.3.8 UART Data Register (UARTx_D)

This register is actually two separate registers. Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register.

NOTE

- In 8-bit or 9-bit data format, only UART data register (D) needs to be accessed to clear the S1[RDRF] bit (assuming receiver buffer level is less than RWFIFO[RXWATER]). The C3 register needs to be read, prior to the D register, only if the ninth bit of data needs to be captured. Similarly, the ED register needs to be read, prior to the D register, only if the additional flag data for the dataword needs to be captured.
- In the normal 8-bit mode (M bit cleared) if the parity is enabled, you get seven data bits and one parity bit. That one parity bit is loaded into the D register. So, for the data

bits, mask off the parity bit from the value you read out of this register.

- When transmitting in 9-bit data format and using 8-bit write instructions, write first to transmit bit 8 in UART control register 3 (C3[T8]), then D. A write to C3[T8] stores the data in a temporary register. If D register is written first, and then the new data on data bus is stored in D, the temporary value written by the last write to C3[T8] gets stored in the C3[T8] register.

Address: Base address + 7h offset

Bit	7	6	5	4	3	2	1	0
Read / Write	RT							
Reset	0	0	0	0	0	0	0	0

UARTx_D field descriptions

Field	Description
7–0 RT	Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register.

49.3.9 UART Match Address Registers 1 (UARTx_MA1)

The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. These registers can be read and written at anytime.

Address: Base address + 8h offset

Bit	7	6	5	4	3	2	1	0
Read / Write	MA							
Reset	0	0	0	0	0	0	0	0

UARTx_MA1 field descriptions

Field	Description
7–0 MA	Match Address

49.3.10 UART Match Address Registers 2 (UARTx_MA2)

These registers can be read and written at anytime. The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded.

Address: Base address + 9h offset

Bit	7	6	5	4	3	2	1	0
Read / Write	MA							
Reset	0	0	0	0	0	0	0	0

UARTx_MA2 field descriptions

Field	Description
7–0 MA	Match Address

49.3.11 UART Control Register 4 (UARTx_C4)

Address: Base address + Ah offset

Bit	7	6	5	4	3	2	1	0
Read / Write	MAEN1	MAEN2	M10	BRFA				
Reset	0	0	0	0	0	0	0	0

UARTx_C4 field descriptions

Field	Description
7 MAEN1	Match Address Mode Enable 1 See Match address operation for more information. 0 All data received is transferred to the data buffer if MAEN2 is cleared. 1 All data received with the most significant bit cleared, is discarded. All data received with the most significant bit set, is compared with contents of MA1 register. If no match occurs, the data is discarded. If match occurs, data is transferred to the data buffer. This field must be cleared when C7816[ISO7816E] is set/enabled.
6 MAEN2	Match Address Mode Enable 2 See Match address operation for more information. 0 All data received is transferred to the data buffer if MAEN1 is cleared. 1 All data received with the most significant bit cleared, is discarded. All data received with the most significant bit set, is compared with contents of MA2 register. If no match occurs, the data is discarded. If a match occurs, data is transferred to the data buffer. This field must be cleared when C7816[ISO7816E] is set/enabled.

Table continues on the next page...

UARTx_C4 field descriptions (continued)

Field	Description
5 M10	10-bit Mode select Causes a tenth, non-memory mapped bit to be part of the serial transmission. This tenth bit is generated and interpreted as a parity bit. The M10 field does not affect the LIN send or detect break behavior. If M10 is set, then both C1[M] and C1[PE] must also be set. This field must be cleared when C7816[ISO7816E] is set/enabled. See Data format (non ISO-7816) for more information. 0 The parity bit is the ninth bit in the serial transmission. 1 The parity bit is the tenth bit in the serial transmission.
4–0 BRFA	Baud Rate Fine Adjust This bit field is used to add more timing resolution to the average baud frequency, in increments of 1/32. See Baud rate generation for more information.

49.3.12 UART Control Register 5 (UARTx_C5)

Address: Base address + Bh offset

Bit	7	6	5	4	3	2	1	0
Read	TDMAS	0	RDMAS	0	0			
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_C5 field descriptions

Field	Description
7 TDMAS	Transmitter DMA Select Configures the transmit data register empty flag, S1[TDRE], to generate interrupt or DMA requests if C2[TIE] is set. **NOTE:** • If C2[TIE] is cleared, TDRE DMA and TDRE interrupt request signals are not asserted when the TDRE flag is set, regardless of the state of TDMAS. • If C2[TIE] and TDMAS are both set, then C2[TCIE] must be cleared, and D must not be written unless a DMA request is being serviced. 0 If C2[TIE] is set and the S1[TDRE] flag is set, the TDRE interrupt request signal is asserted to request interrupt service. 1 If C2[TIE] is set and the S1[TDRE] flag is set, the TDRE DMA request signal is asserted to request a DMA transfer.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 RDMAS	Receiver Full DMA Select Configures the receiver data register full flag, S1[RDRF], to generate interrupt or DMA requests if C2[RIE] is set. **NOTE:** If C2[RIE] is cleared, and S1[RDRF] is set, the RDRF DMA and RDFR interrupt request signals are not asserted, regardless of the state of RDMAS.

Table continues on the next page...

UARTx_C5 field descriptions (continued)

Field	Description
	0 If C2[RIE] and S1[RDRF] are set, the RDFR interrupt request signal is asserted to request an interrupt service. 1 If C2[RIE] and S1[RDRF] are set, the RDRF DMA request signal is asserted to request a DMA transfer.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

49.3.13 UART Extended Data Register (UARTx_ED)

This register contains additional information flags that are stored with a received dataword. This register may be read at any time but contains valid data only if there is a dataword in the receive FIFO.

NOTE

- The data contained in this register represents additional information regarding the conditions on which a dataword was received. The importance of this data varies with the application, and in some cases maybe completely optional. These fields automatically update to reflect the conditions of the next dataword whenever D is read.
- If S1[NF] and S1[PF] have not been set since the last time the receive buffer was empty, the NOISY and PARITYE fields will be zero.

Address: Base address + Ch offset

Bit	7	6	5	4	3	2	1	0
Read	NOISY	PARITYE	0					
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_ED field descriptions

Field	Description
7 NOISY	The current received dataword contained in D and C3[R8] was received with noise. 0 The dataword was received without noise. 1 The data was received with noise.
6 PARITYE	The current received dataword contained in D and C3[R8] was received with a parity error. 0 The dataword was received without a parity error. 1 The dataword was received with a parity error.

Table continues on the next page...

UARTx_ED field descriptions (continued)

Field	Description
5–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

49.3.14 UART Modem Register (UARTx_MODEM)

The MODEM register controls options for setting the modem configuration.

NOTE

RXRTSE, TXRTSPOL, TXRTSE, and TXCTSE must all be cleared when C7816[ISO7816EN] is enabled. This will cause the RTS to deassert during ISO-7816 wait times. The ISO-7816 protocol does not use the RTS and CTS signals.

Address: Base address + Dh offset

Bit	7	6	5	4	3	2	1	0
Read	0				RXRTSE	TXRTSPOL	TXRTSE	TXCTSE
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_MODEM field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 RXRTSE	Receiver request-to-send enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. **NOTE:** Do not set both RXRTSE and TXRTSE. 0 The receiver has no effect on RTS. 1 RTS is deasserted if the number of characters in the receiver data register (FIFO) is equal to or greater than RWFIFO[RXWATER]. RTS is asserted when the number of characters in the receiver data register (FIFO) is less than RWFIFO[RXWATER].
2 TXRTSPOL	Transmitter request-to-send polarity Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. 0 Transmitter RTS is active low. 1 Transmitter RTS is active high.
1 TXRTSE	Transmitter request-to-send enable Controls RTS before and after a transmission.

Table continues on the next page...

UARTx_MODEM field descriptions (continued)

Field	Description
	0 The transmitter has no effect on RTS. 1 When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. (FIFO)(FIFO)
0 TXCTSE	Transmitter clear-to-send enable TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE. 0 CTS has no effect on the transmitter. 1 Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission.

49.3.15 UART Infrared Register (UARTx_IR)

The IR register controls options for setting the infrared configuration.

Address: Base address + Eh offset

Bit	7	6	5	4	3	2	1	0
Read	0					IREN	TNP	
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_IR field descriptions

Field	Description
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 IREN	Infrared enable Enables/disables the infrared modulation/demodulation. 0 IR disabled. 1 IR enabled.
1–0 TNP	Transmitter narrow pulse Enables whether the UART transmits a 1/16, 3/16, 1/32, or 1/4 narrow pulse. 00 3/16. 01 1/16. 10 1/32. 11 1/4.

49.3.16 UART FIFO Parameters (UARTx_PFIFO)

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when C2[RE] and C2[TE] are cleared/not set and when the data buffer/FIFO is empty.

Address: Base address + 10h offset

Bit	7	6	5	4	3	2	1	0
Read	TXFE	TXFIFOSIZE			RXFE	RXFIFOSIZE		
Write								
Reset	0	*	*	*	0	*	*	*

* Notes:

- TXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.
- RXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.

UARTx_PFIFO field descriptions

Field	Description
7 TXFE	Transmit FIFO Enable When this field is set, the built in FIFO structure for the transmit buffer is enabled. The size of the FIFO structure is indicated by TXFIFOSIZE. If this field is not set, the transmit buffer operates as a FIFO of depth one dataword regardless of the value in TXFIFOSIZE. Both C2[TE] and C2[RE] must be cleared prior to changing this field. Additionally, TXFLUSH and RXFLUSH commands must be issued immediately after changing this field. 0 Transmit FIFO is not enabled. Buffer is depth 1. (Legacy support). 1 Transmit FIFO is enabled. Buffer is depth indicated by TXFIFOSIZE.
6–4 TXFIFOSIZE	Transmit FIFO. Buffer Depth The maximum number of transmit datawords that can be stored in the transmit buffer. This field is read only. 000 Transmit FIFO/Buffer depth = 1 dataword. 001 Transmit FIFO/Buffer depth = 4 datawords. 010 Transmit FIFO/Buffer depth = 8 datawords. 011 Transmit FIFO/Buffer depth = 16 datawords. 100 Transmit FIFO/Buffer depth = 32 datawords. 101 Transmit FIFO/Buffer depth = 64 datawords. 110 Transmit FIFO/Buffer depth = 128 datawords. 111 Reserved.
3 RXFE	Receive FIFO Enable

Table continues on the next page...

UARTx_PFIFO field descriptions (continued)

Field	Description
	When this field is set, the built in FIFO structure for the receive buffer is enabled. The size of the FIFO structure is indicated by the RXFIFOSIZE field. If this field is not set, the receive buffer operates as a FIFO of depth one dataword regardless of the value in RXFIFOSIZE. Both C2[TE] and C2[RE] must be cleared prior to changing this field. Additionally, TXFLUSH and RXFLUSH commands must be issued immediately after changing this field. 0 Receive FIFO is not enabled. Buffer is depth 1. (Legacy support) 1 Receive FIFO is enabled. Buffer is depth indicted by RXFIFOSIZE.
2–0 RXFIFOSIZE	Receive FIFO. Buffer Depth The maximum number of receive datawords that can be stored in the receive buffer before an overrun occurs. This field is read only. 000 Receive FIFO/Buffer depth = 1 dataword. 001 Receive FIFO/Buffer depth = 4 datawords. 010 Receive FIFO/Buffer depth = 8 datawords. 011 Receive FIFO/Buffer depth = 16 datawords. 100 Receive FIFO/Buffer depth = 32 datawords. 101 Receive FIFO/Buffer depth = 64 datawords. 110 Receive FIFO/Buffer depth = 128 datawords. 111 Reserved.

49.3.17 UART FIFO Control Register (UARTx_CFIFO)

This register provides the ability to program various control fields for FIFO operation. This register may be read or written at any time. Note that writing to TXFLUSH and RXFLUSH may result in data loss and requires careful action to prevent unintended/ unpredictable behavior. Therefore, it is recommended that TE and RE be cleared prior to flushing the corresponding FIFO.

Address: Base address + 11h offset

Bit	7	6	5	4	3	2	1	0
Read	0	0	0			RXOFE	TXOFE	RXUFE
Write	TXFLUSH	RXFLUSH						
Reset	0	0	0	0	0	0	0	0

UARTx_CFIFO field descriptions

Field	Description
7 TXFLUSH	Transmit FIFO/Buffer Flush Writing to this field causes all data that is stored in the transmit FIFO/buffer to be flushed. This does not affect data that is in the transmit shift register. 0 No flush operation occurs. 1 All data in the transmit FIFO/Buffer is cleared out.

Table continues on the next page...

UARTx_CFIFO field descriptions (continued)

Field	Description
6 RXFLUSH	Receive FIFO/Buffer Flush Writing to this field causes all data that is stored in the receive FIFO/buffer to be flushed. This does not affect data that is in the receive shift register. 0 No flush operation occurs. 1 All data in the receive FIFO/buffer is cleared out.
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 RXOFE	Receive FIFO Overflow Interrupt Enable When this field is set, the RXOF flag generates an interrupt to the host. 0 RXOF flag does not generate an interrupt to the host. 1 RXOF flag generates an interrupt to the host.
1 TXOFE	Transmit FIFO Overflow Interrupt Enable When this field is set, the TXOF flag generates an interrupt to the host. 0 TXOF flag does not generate an interrupt to the host. 1 TXOF flag generates an interrupt to the host.
0 RXUFE	Receive FIFO Underflow Interrupt Enable When this field is set, the RXUF flag generates an interrupt to the host. 0 RXUF flag does not generate an interrupt to the host. 1 RXUF flag generates an interrupt to the host.

49.3.18 UART FIFO Status Register (UARTx_SFIFO)

This register provides status information regarding the transmit and receiver buffers/ FIFOs, including interrupt information. This register may be written to or read at any time.

Address: Base address + 12h offset

Bit	7	6	5	4	3	2	1	0
Read	TXEMPT	RXEMPT	0			RXOF	TXOF	RXUF
Write						w1c	w1c	w1c
Reset	1	1	0	0	0	0	0	0

UARTx_SFIFO field descriptions

Field	Description
7 TXEMPT	Transmit Buffer/FIFO Empty Asserts when there is no data in the Transmit FIFO/buffer. This field does not take into account data that is in the transmit shift register.

Table continues on the next page...

UARTx_SFIFO field descriptions (continued)

Field	Description
	0 Transmit buffer is not empty. 1 Transmit buffer is empty.
6 RXEMPT	Receive Buffer/FIFO Empty Asserts when there is no data in the receive FIFO/Buffer. This field does not take into account data that is in the receive shift register. 0 Receive buffer is not empty. 1 Receive buffer is empty.
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 RXOF	Receiver Buffer Overflow Flag Indicates that more data has been written to the receive buffer than it can hold. This field will assert regardless of the value of CFIFO[RXOFE]. However, an interrupt will be issued to the host only if CFIFO[RXOFE] is set. This flag is cleared by writing a 1. 0 No receive buffer overflow has occurred since the last time the flag was cleared. 1 At least one receive buffer overflow has occurred since the last time the flag was cleared.
1 TXOF	Transmitter Buffer Overflow Flag Indicates that more data has been written to the transmit buffer than it can hold. This field will assert regardless of the value of CFIFO[TXOFE]. However, an interrupt will be issued to the host only if CFIFO[TXOFE] is set. This flag is cleared by writing a 1. 0 No transmit buffer overflow has occurred since the last time the flag was cleared. 1 At least one transmit buffer overflow has occurred since the last time the flag was cleared.
0 RXUF	Receiver Buffer Underflow Flag Indicates that more data has been read from the receive buffer than was present. This field will assert regardless of the value of CFIFO[RXUFE]. However, an interrupt will be issued to the host only if CFIFO[RXUFE] is set. This flag is cleared by writing a 1. 0 No receive buffer underflow has occurred since the last time the flag was cleared. 1 At least one receive buffer underflow has occurred since the last time the flag was cleared.

49.3.19 UART FIFO Transmit Watermark (UARTx_TWFIFO)

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when C2[TE] is not set. Changing the value of the watermark will not clear the S1[TDRE] flag.

Address: Base address + 13h offset

Bit	7	6	5	4	3	2	1	0
Read Write	TXWATER							
Reset	0	0	0	0	0	0	0	0

UARTx_TWFIFO field descriptions

Field	Description
7–0 TXWATER	Transmit Watermark When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt via S1[TDRE] or a DMA request via C5[TDMAS] is generated as determined by C5[TDMAS] and C2[TIE]. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by PFIFO[TXFIFOSIZE] and PFIFO[TXFE].

49.3.20 UART FIFO Transmit Count (UARTx_TCFIFO)

This is a read only register that indicates how many datawords are currently in the transmit buffer/FIFO. It may be read at any time.

Address: Base address + 14h offset

Bit	7	6	5	4	3	2	1	0
Read	TXCOUNT							
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_TCFIFO field descriptions

Field	Description
7–0 TXCOUNT	Transmit Counter The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with PFIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.

49.3.21 UART FIFO Receive Watermark (UARTx_RWFIFO)

This register provides the ability to set a programmable threshold for notification of the need to remove data from the receiver FIFO/buffer. This register may be read at any time but must be written only when C2[RE] is not asserted. Changing the value in this register will not clear S1[RDRF].

Address: Base address + 15h offset

Bit	7	6	5	4	3	2	1	0
Read Write	RXWATER							
Reset	0	0	0	0	0	0	0	1

UARTx_RWFIFO field descriptions

Field	Description
7–0 RXWATER	Receive Watermark When the number of datawords in the receive FIFO/buffer is equal to or greater than the value in this register field, an interrupt via S1[RDRF] or a DMA request via C5[RDMAS] is generated as determined by C5[RDMAS] and C2[RIE]. For proper operation, the value in RXWATER must be set to be less than the receive FIFO/buffer size as indicated by PFIFO[RXFIFOSIZE] and PFIFO[RXFE] and must be greater than 0.

49.3.22 UART FIFO Receive Count (UARTx_RCFIFO)

This is a read only register that indicates how many datawords are currently in the receive FIFO/buffer. It may be read at any time.

Address: Base address + 16h offset

Bit	7	6	5	4	3	2	1	0
Read	RXCOUNT							
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_RCFIFO field descriptions

Field	Description
7–0 RXCOUNT	Receive Counter The value in this register indicates the number of datawords that are in the receive FIFO/buffer. If a dataword is being received, that is, in the receive shift register, it is not included in the count. This value may be used in conjunction with PFIFO[RXFIFOSIZE] to calculate how much room is left in the receive FIFO/buffer.

49.3.23 UART 7816 Control Register (UARTx_C7816)

The C7816 register is the primary control register for ISO-7816 specific functionality. This register is specific to 7816 functionality and the values in this register have no effect on UART operation and should be ignored if ISO_7816E is not set/enabled. This register may be read at any time but values must be changed only when ISO_7816E is not set.

Address: Base address + 18h offset

Bit	7	6	5	4	3	2	1	0
Read	0			ONACK	ANACK	INIT	TTYPE	ISO_7816E
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_C7816 field descriptions

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 ONACK	Generate NACK on Overflow When this field is set, the receiver automatically generates a NACK response if a receive buffer overrun occurs, as indicated by S1[OR]. In many systems, this results in the transmitter resending the packet that overflowed until the retransmit threshold for that transmitter is reached. A NACK is generated only if TTYPE=0. This field operates independently of ANACK. See . Overrun NACK considerations 0 The received data does not generate a NACK when the receipt of the data results in an overflow event. 1 If the receiver buffer overflows, a NACK is automatically sent on a received character.
3 ANACK	Generate NACK on Error When this field is set, the receiver automatically generates a NACK response if a parity error occurs or if INIT is set and an invalid initial character is detected. A NACK is generated only if TTYPE = 0. If ANACK is set, the UART attempts to retransmit the data indefinitely. To stop retransmission attempts, clear C2[TE] or ISO_7816E and do not set until S1[TC] sets C2[TE] again. 0 No NACK is automatically generated. 1 A NACK is automatically generated if a parity error is detected or if an invalid initial character is detected.
2 INIT	Detect Initial Character When this field is set, all received characters are searched for a valid initial character. If an invalid initial character is identified, and ANACK is set, a NACK is sent. All received data is discarded and error flags blocked (S1[NF], S1[OR], S1[FE], S1[PF], IS7816[WT], IS7816[CWT], IS7816[BWT], IS7816[GTV]) until a valid initial character is detected. Upon detecting a valid initial character, the configuration values S2[MSBF], C3[TXINV], and S2[RXINV] are automatically updated to reflect the initial character that was received. The actual INIT data value is not stored in the receive buffer. Additionally, upon detection of a valid initial character, IS7816[INITD] is set and an interrupt issued as programmed by IE7816[INITDE]. When a valid initial character is detected, INIT is automatically cleared. This Initial Character Detect feature is supported only in T = 0 protocol mode. 0 Normal operating mode. Receiver does not seek to identify initial character. 1 Receiver searches for initial character.
1 TTYPE	Transfer Type Indicates the transfer protocol being used. See ISO-7816 / smartcard support for more details. 0 T = 0 per the ISO-7816 specification. 1 T = 1 per the ISO-7816 specification.
0 ISO_7816E	ISO-7816 Functionality Enabled Indicates that the UART is operating according to the ISO-7816 protocol. **NOTE:** This field must be modified only when no transmit or receive is occurring. If this field is changed during a data transfer, the data being transmitted or received may be transferred incorrectly. 0 ISO-7816 functionality is turned off/not enabled. 1 ISO-7816 functionality is turned on/enabled.

49.3.24 UART 7816 Interrupt Enable Register (UARTx_IE7816)

The IE7816 register controls which flags result in an interrupt being issued. This register is specific to 7816 functionality, the corresponding flags that drive the interrupts are not asserted when 7816E is not set/enabled. However, these flags may remain set if they are asserted while 7816E was set and not subsequently cleared. This register may be read or written to at any time.

Address: Base address + 19h offset

Bit	7	6	5	4	3	2	1	0
Read	WTE	CWTE	BWTE	INITDE	0	GTVE	TXTE	RXTE
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_IE7816 field descriptions

Field	Description
7 WTE	Wait Timer Interrupt Enable 0 The assertion of IS7816[WT] does not result in the generation of an interrupt. 1 The assertion of IS7816[WT] results in the generation of an interrupt.
6 CWTE	Character Wait Timer Interrupt Enable 0 The assertion of IS7816[CWT] does not result in the generation of an interrupt. 1 The assertion of IS7816[CWT] results in the generation of an interrupt.
5 BWTE	Block Wait Timer Interrupt Enable 0 The assertion of IS7816[BWT] does not result in the generation of an interrupt. 1 The assertion of IS7816[BWT] results in the generation of an interrupt.
4 INITDE	Initial Character Detected Interrupt Enable 0 The assertion of IS7816[INITD] does not result in the generation of an interrupt. 1 The assertion of IS7816[INITD] results in the generation of an interrupt.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 GTVE	Guard Timer Violated Interrupt Enable 0 The assertion of IS7816[GTV] does not result in the generation of an interrupt. 1 The assertion of IS7816[GTV] results in the generation of an interrupt.
1 TXTE	Transmit Threshold Exceeded Interrupt Enable 0 The assertion of IS7816[TXT] does not result in the generation of an interrupt. 1 The assertion of IS7816[TXT] results in the generation of an interrupt.
0 RXTE	Receive Threshold Exceeded Interrupt Enable 0 The assertion of IS7816[RXT] does not result in the generation of an interrupt. 1 The assertion of IS7816[RXT] results in the generation of an interrupt.

49.3.25 UART 7816 Interrupt Status Register (UARTx_IS7816)

The IS7816 register provides a mechanism to read and clear the interrupt flags. All flags/interrupts are cleared by writing a 1 to the field location. Writing a 0 has no effect. All bits are "sticky", meaning they indicate that only the flag condition that occurred since the last time the bit was cleared, not that the condition currently exists. The status flags are set regardless of whether the corresponding field in the IE7816 is set or cleared. The IE7816 controls only if an interrupt is issued to the host processor. This register is specific to 7816 functionality and the values in this register have no affect on UART operation and should be ignored if 7816E is not set/enabled. This register may be read or written at anytime.

Address: Base address + 1Ah offset

Bit	7	6	5	4	3	2	1	0
Read	WT	CWT	BWT	INITD	0	GTV	TXT	RXT
Write	w1c	w1c	w1c	w1c		w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

UARTx_IS7816 field descriptions

Field	Description
7 WT	Wait Timer Interrupt Indicates that the wait time, the time between the leading edge of a character being transmitted and the leading edge of the next response character, has exceeded the programmed value. This flag asserts only when C7816[TTYPE] = 0. This interrupt is cleared by writing 1. 0 Wait time (WT) has not been violated. 1 Wait time (WT) has been violated.
6 CWT	Character Wait Timer Interrupt Indicates that the character wait time, the time between the leading edges of two consecutive characters in a block, has exceeded the programmed value. This flag asserts only when C7816[TTYPE] = 1. This interrupt is cleared by writing 1. 0 Character wait time (CWT) has not been violated. 1 Character wait time (CWT) has been violated.
5 BWT	Block Wait Timer Interrupt Indicates that the block wait time, the time between the leading edge of first received character of a block and the leading edge of the last character the previously transmitted block, has exceeded the programmed value. This flag asserts only when C7816[TTYPE] = 1.This interrupt is cleared by writing 1. 0 Block wait time (BWT) has not been violated. 1 Block wait time (BWT) has been violated.
4 INITD	Initial Character Detected Interrupt Indicates that a valid initial character is received. This interrupt is cleared by writing 1.

Table continues on the next page...

UARTx_IS7816 field descriptions (continued)

Field	Description
	0 A valid initial character has not been received. 1 A valid initial character has been received.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 GTV	Guard Timer Violated Interrupt Indicates that one or more of the character guard time, block guard time, or guard time are violated. This interrupt is cleared by writing 1. 0 A guard time (GT, CGT, or BGT) has not been violated. 1 A guard time (GT, CGT, or BGT) has been violated.
1 TXT	Transmit Threshold Exceeded Interrupt Indicates that the transmit NACK threshold has been exceeded as indicated by ET7816[TXTHRESHOLD]. Regardless of whether this flag is set, the UART continues to retransmit indefinitely. This flag asserts only when C7816[TTYPE] = 0. If 7816E is cleared/disabled, ANACK is cleared/disabled, C2[TE] is cleared/disabled, C7816[TTYPE] = 1, or packet is transferred without receiving a NACK, the internal NACK detection counter is cleared and the count restarts from zero on the next received NACK. This interrupt is cleared by writing 1. 0 The number of retries and corresponding NACKS does not exceed the value in ET7816[TXTHRESHOLD]. 1 The number of retries and corresponding NACKS exceeds the value in ET7816[TXTHRESHOLD].
0 RXT	Receive Threshold Exceeded Interrupt Indicates that there are more than ET7816[RXTHRESHOLD] consecutive NACKS generated in response to parity errors on received data. This flag requires ANACK to be set. Additionally, this flag asserts only when C7816[TTYPE] = 0. Clearing this field also resets the counter keeping track of consecutive NACKS. The UART will continue to attempt to receive data regardless of whether this flag is set. If 7816E is cleared/disabled, RE is cleared/disabled, C7816[TTYPE] = 1, or packet is received without needing to issue a NACK, the internal NACK detection counter is cleared and the count restarts from zero on the next transmitted NACK. This interrupt is cleared by writing 1. 0 The number of consecutive NACKS generated as a result of parity errors and buffer overruns is less than or equal to the value in ET7816[RXTHRESHOLD]. 1 The number of consecutive NACKS generated as a result of parity errors and buffer overruns is greater than the value in ET7816[RXTHRESHOLD].

49.3.26 UART 7816 Wait Parameter Register (UARTx_WP7816T0)

The WP7816 register contains constants used in the generation of various wait timer counters. To save register space, this register is used differently when C7816[TTYPE] = 0 and C7816[TTYPE] = 1. This register may be read at any time. This register must be written to only when C7816[ISO_7816E] is not set.

Address: Base address + 1Bh offset

Bit	7	6	5	4	3	2	1	0
Read Write	WI							
Reset	0	0	0	0	1	0	1	0

UARTx_WP7816T0 field descriptions

Field	Description
7–0 WI	Wait Time Integer (C7816[TTYPE] = 0) Used to calculate the value used for the WT counter. It represents a value between 1 and 255. The value of zero is not valid. This value is used only when C7816[TTYPE] = 0. See Wait time and guard time parameters.

49.3.27 UART 7816 Wait Parameter Register (UARTx_WP7816T1)

The WP7816 register contains constants used in the generation of various wait timer counters. To save register space, this register is used differently when C7816[TTYPE] = 0 and C7816[TTYPE] = 1. This register may be read at any time. This register must be written to only when C7816[ISO_7816E] is not set.

Address: Base address + 1Bh offset

Bit	7	6	5	4	3	2	1	0
Read Write	CWI				BWI			
Reset	0	0	0	0	1	0	1	0

UARTx_WP7816T1 field descriptions

Field	Description
7–4 CWI	Character Wait Time Integer (C7816[TTYPE] = 1) Used to calculate the value used for the CWT counter. It represents a value between 0 and 15. This value is used only when C7816[TTYPE] = 1. See Wait time and guard time parameters .
3–0 BWI	Block Wait Time Integer(C7816[TTYPE] = 1) Used to calculate the value used for the BWT counter. It represent a value between 0 and 15. This value is used only when C7816[TTYPE] = 1. See Wait time and guard time parameters .

49.3.28 UART 7816 Wait N Register (UARTx_WN7816)

The WN7816 register contains a parameter that is used in the calculation of the guard time counter. This register may be read at any time. This register must be written to only when C7816[ISO_7816E] is not set.

Address: Base address + 1Ch offset

Bit	7	6	5	4	3	2	1	0
Read Write	GTN							
Reset	0	0	0	0	0	0	0	0

UARTx_WN7816 field descriptions

Field	Description
7–0 GTN	Guard Band N Defines a parameter used in the calculation of GT, CGT, and BGT counters. The value represents an integer number between 0 and 255. See Wait time and guard time parameters .

49.3.29 UART 7816 Wait FD Register (UARTx_WF7816)

The WF7816 contains parameters that are used in the generation of various counters including GT, CGT, BGT, WT, and BWT. This register may be read at any time. This register must be written to only when C7816[ISO_7816E] is not set.

Address: Base address + 1Dh offset

Bit	7	6	5	4	3	2	1	0
Read Write	GTFD							
Reset	0	0	0	0	0	0	0	1

UARTx_WF7816 field descriptions

Field	Description
7–0 GTFD	FD Multiplier Used as another multiplier in the calculation of WT and BWT. This value represents a number between 1 and 255. The value of 0 is invalid. This value is not used in baud rate generation. See Wait time and guard time parameters and Baud rate generation .

49.3.30 UART 7816 Error Threshold Register (UARTx_ET7816)

The ET7816 register contains fields that determine the number of NACKs that must be received or transmitted before the host processor is notified. This register may be read at anytime. This register must be written to only when C7816[ISO_7816E] is not set.

Address: Base address + 1Eh offset

Bit	7	6	5	4	3	2	1	0
Read Write	TXTHRESHOLD				RXTHRESHOLD			
Reset	0	0	0	0	0	0	0	0

UARTx_ET7816 field descriptions

Field	Description
7–4 TXTHRESHOLD	Transmit NACK Threshold The value written to this field indicates the maximum number of failed attempts (NACKs) a transmitted character can have before the host processor is notified. This field is meaningful only when

Table continues on the next page...

UARTx_ET7816 field descriptions (continued)

Field	Description
	C7816[TTYPE] = 0 and C7816[ANACK] = 1. The value read from this field represents the number of consecutive NACKs that have been received since the last successful transmission. This counter saturates at 4'hF and does not wrap around. Regardless of how many NACKs that are received, the UART continues to retransmit indefinitely. This flag only asserts when C7816[TTYPE] = 0. For additional information see the IS7816[TXT] field description. 0 TXT asserts on the first NACK that is received. 1 TXT asserts on the second NACK that is received.
3–0 RXTHRESHOLD	Receive NACK Threshold The value written to this field indicates the maximum number of consecutive NACKs generated as a result of a parity error or receiver buffer overruns before the host processor is notified. After the counter exceeds that value in the field, the IS7816[RXT] is asserted. This field is meaningful only when C7816[TTYPE] = 0. The value read from this field represents the number of consecutive NACKs that have been transmitted since the last successful reception. This counter saturates at 4'hF and does not wrap around. Regardless of the number of NACKs sent, the UART continues to receive valid packets indefinitely. For additional information, see IS7816[RXT] field description.

49.3.31 UART 7816 Transmit Length Register (UARTx_TL7816)

The TL7816 register is used to indicate the number of characters contained in the block being transmitted. This register is used only when C7816[TTYPE] = 1. This register may be read at anytime. This register must be written only when C2[TE] is not enabled.

Address: Base address + 1Fh offset

Bit	7	6	5	4	3	2	1	0
Read Write	TLEN							
Reset	0	0	0	0	0	0	0	0

UARTx_TL7816 field descriptions

Field	Description
7–0 TLEN	Transmit Length This value plus four indicates the number of characters contained in the block being transmitted. This register is automatically decremented by 1 for each character in the information field portion of the block. Additionally, this register is automatically decremented by 1 for the first character of a CRC in the epilogue field. Therefore, this register must be programmed with the number of bytes in the data packet if an LRC is being transmitted, and the number of bytes + 1 if a CRC is being transmitted. This register is not decremented for characters that are assumed to be part of the Prologue field, that is, the first three characters transmitted in a block, or the LRC or last CRC character in the Epilogue field, that is, the last character transmitted. This field must be programed or adjusted only when C2[TE] is cleared.

49.3.32 UART CEA709.1-B Control Register 6 (UARTx_C6)

Address: Base address + 21h offset

Bit	7	6	5	4	3	2	1	0
Read / Write	EN709	TX709	CE	CP	0			
Reset	0	0	0	0	0	0	0	0

UARTx_C6 field descriptions

Field	Description
7 EN709	EN709 Enables the CEA709.1-B feature. 0 CEA709.1-B is disabled. 1 CEA709.1-B is enabled
6 TX709	CEA709.1-B Transmit Enable Starts CEA709.1-B transmission. This bit is automatically cleared after completely transmitting the packet 0 CEA709.1-B transmitter is disabled. 1 CEA709.1-B transmitter is enabled.
5 CE	Collision Enable Enables the collision detect functionality. 0 Collision detect feature is disabled. 1 Collision detect feature is enabled.
4 CP	Collision Signal Polarity Indicates the polarity of the collision signal. 0 Collision signal is active low. 1 Collision signal is active high.
3–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

49.3.33 UART CEA709.1-B Packet Cycle Time Counter High (UARTx_PCTH)

Address: Base address + 22h offset

Bit	7	6	5	4	3	2	1	0
Read / Write	PCTH							
Reset	0	0	0	0	0	0	0	0

UARTx_PCTH field descriptions

Field	Description
7–0 PCTH	Packet Cycle Time Counter High Indicates the most significant byte of maximum period after the line code violation (B1 and SDT expired) for which the bus could remain idle without decrementing back log count. If the time elapsed after line code violation (B1 and SDT expired) is greater than packet cycle time, then packet cycle timer expired interrupt is generated. It is measured in terms of bit times, that is, the time it takes for a single bit or one differential Manchester symbol to be transmitted. This is medium dependent and hence does not usually require adjustment and is programmed only once.

49.3.34 UART CEA709.1-B Packet Cycle Time Counter Low (UARTx_PCTL)

Address: Base address + 23h offset

Bit	7	6	5	4	3	2	1	0
Read Write	PCTL							
Reset	0	0	0	0	0	0	0	0

UARTx_PCTL field descriptions

Field	Description
7–0 PCTL	Packet Cycle Time Counter Low Indicates the least significant byte of maximum period after the line code violation (B1 and SDT expired) for which the bus could remain idle without decrementing back log count. If the time elapsed after line code violation (B1 and SDT expired) is greater than packet cycle time, then packet cycle timer expired interrupt is generated. It is measured in terms of bit times, that is, the time it takes for a single bit or one Differential Manchester symbol to be transmitted. This is medium dependent and therefore does not usually require adjustment and is programmed only once.

49.3.35 UART CEA709.1-B Beta1 Timer (UARTx_B1T)

Address: Base address + 24h offset

Bit	7	6	5	4	3	2	1	0
Read Write	B1T							
Reset	0	0	0	0	0	0	0	0

UARTx_B1T field descriptions

Field	Description
7–0 B1T	Beta1 Timer Beta1 delay is a value that is system dependent and usually does not require adjustment. It is programmed only once and measured in bit times.

49.3.36 UART CEA709.1-B Secondary Delay Timer High (UARTx_SDTH)

Address: Base address + 25h offset

Bit	7	6	5	4	3	2	1	0
Read Write	SDTH							
Reset	0	0	0	0	0	0	0	0

UARTx_SDTH field descriptions

Field	Description
7–0 SDTH	Secondary Delay Timer High This is the most significant byte of the secondary delay timer and is set by software. This is generally a variable value that must be set for each data message to be transmitted. It is measured in bit times, that is, the time that it takes for a single bit or one differential Manchester symbol to be transmitted. This value must be between 0 and (BL*Wbase) + (ProritySlots -1), Beta2 timeslots. A value of zero indicates that the queued packet will be sent immediately upon expiration of the beta1 timer.

49.3.37 UART CEA709.1-B Secondary Delay Timer Low (UARTx_SDTL)

Address: Base address + 26h offset

Bit	7	6	5	4	3	2	1	0
Read Write	SDTL							
Reset	0	0	0	0	0	0	0	0

UARTx_SDTL field descriptions

Field	Description
7–0 SDTL	Secondary Delay Timer Low This is the least significant byte of the secondary delay timer and is set by software. This is generally a variable value that must be set for each data message to be transmitted. It is measured in bit times, that is, the time that it takes for a single bit or one Differential Manchester symbol to be transmitted. This value must be between 0 and (BL*Wbase) + (ProritySlots -1), Beta2 timeslots. A value of zero indicates that the queued packet will be sent immediately upon expiration of the Beta1 timer.

49.3.38 UART CEA709.1-B Preamble (UARTx_PRE)

Address: Base address + 27h offset

Bit	7	6	5	4	3	2	1	0
Read Write	PREAMBLE							
Reset	0	0	0	0	0	0	0	0

UARTx_PRE field descriptions

Field	Description
7–0 PREAMBLE	CEA709.1-B Preamble Register The number of bit-sync characters that occur prior to the byte-sync character when preamble is transmitted. **NOTE:** The minimum preamble length supported by twisted pair wire is four bit-sync fields.

49.3.39 UART CEA709.1-B Transmit Packet Length (UARTx_TPL)

Address: Base address + 28h offset

Bit	7	6	5	4	3	2	1	0
Read Write	TPL							
Reset	0	0	0	0	0	0	0	0

UARTx_TPL field descriptions

Field	Description
7–0 TPL	Transmit Packet Length Register Length of the data packet in bytes that is transmitted by CEA709.1-B transmitter. This includes the CRC packet as well.

49.3.40 UART CEA709.1-B Interrupt Enable Register (UARTx_IE)

Address: Base address + 29h offset

Bit	7	6	5	4	3	2	1	0
Read	0	WBEIE	ISDIE	PRXIE	PTXIE	PCTEIE	PSIE	TXFIE
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_IE field descriptions

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 WBEIE	WBASE Expired Interrupt Enable Interrupt enable for WBASE expired flag. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 ISDIE	Initial Sync Detection Interrupt Enable Interrupt enable for initial synchronization detection flag.

Table continues on the next page...

UARTx_IE field descriptions (continued)

Field	Description
	NOTE: This field cannot be cleared except by disabling CEA709. Therefore, ISDIE must be cleared when the first initial sync detection interrupt occurs. If the ISD interrupt is not disabled in the interrupt handler, then user will continuously get interrupts. 0 Interrupt is disabled. 1 Interrupt is enabled.
4 PRXIE	Packet Received Interrupt Enable Interrupt enable for packet received flag. 0 Interrupt is disabled. 1 Interrupt is enabled.
3 PTXIE	Packet Transmitted Interrupt Enable Interrupt enable for packet transmitted flag. 0 Interrupt is disabled. 1 Interrupt is enabled.
2 PCTEIE	Packet Cycle Timer Interrupt Enable Interrupt enable for packet cycle time expired flag. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 PSIE	Preamble Start Interrupt Enable Interrupt enable for preamble start flag. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 TXFIE	Transmission Fail Interrupt Enable Interrupt enable for transmission fail flag. 0 Interrupt is disabled. 1 Interrupt is enabled.

49.3.41 UART CEA709.1-B WBASE (UARTx_WB)

Address: Base address + 2Ah offset

Bit	7	6	5	4	3	2	1	0
Read Write	WBASE							
Reset	0	0	0	0	0	0	0	0

UARTx_WB field descriptions

Field	Description
7–0 WBASE	CEA709.1-B WBASE register

UARTx_WB field descriptions (continued)

Field	Description
	Size of the basic randomizing window in bit periods after Beta1 time period. It is measured in bit times.

49.3.42 UART CEA709.1-B Status Register (UARTx_S3)

Address: Base address + 2Bh offset

Bit	7	6	5	4	3	2	1	0
Read	PEF	WBEF	ISD	PRXF	PTXF	PCTEF	PSF	TXFF
Write	w1c	w1c		w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

UARTx_S3 field descriptions

Field	Description
7 PEF	Preamble Error Flag Indicates that the received preamble has an error. If the received preamble length is greater than or less than the transmit preamble length, the preamble error flag is asserted. This flag is cleared by writing 1. 0 Preamble is correct. 1 Preamble has an error.
6 WBEF	Wbase Expired Flag Indicates that the Wbase time period has expired after beta1 time slots. This flag is cleared by writing 1. 0 WBASE time period has not expired. 1 WBASE time period has expired after beta1 time slots.
5 ISD	Initial Sync Detect Indicates that initially, a valid one and a line code violation is detected. This flag is cleared by deasserting EN709 bit. 0 Initial sync is not detected. 1 Initial sync is detected.
4 PRXF	Packet Received Flag Indicates that complete packet is received. This flag is cleared by writing 1. 0 Packet is not received. 1 Packet is received.
3 PTXF	Packet Transmitted Flag Indicates that complete packet is transmitted. This flag is cleared by writing 1. In case TX packet gets aborted due to FIFO becoming empty or an overflow, packet transmitted flag will still be generated. 0 Packet transmission is not complete. 1 Packet transmission is complete.

Table continues on the next page...

UARTx_S3 field descriptions (continued)

Field	Description
2 PCTEF	Packet Cycle Timer Expired Flag Indicates that packet cycle time period has expired with no activity on the line. This flag is cleared by writing 1. 0 Packet cycle time has not expired. 1 Packet cycle time has expired.
1 PSF	Preamble Start Flag Indicates start of the preamble while the packet is being transmitted. This flag is cleared by writing 1. 0 Preamble start is not detected. 1 Preamble start is detected.
0 TXFF	Transmission Fail Flag This flag indicates that transmission could not proceed. This flag is asserted when the packet is queued for transmission but before the random delay is expired an incoming receive packet is detected. This flag is also asserted while transmission when the TX fifo becomes empty or overflows. During these cases Line Code Violation is transmitted on TX line immediately after current byte or preamble transmission is finished, without waiting for completion of transmit packet length. If the transmission fail flag is asserted then TX709 bit of UART_C6 register is cleared. This flag is cleared by writing `1'. 0 Transmission continues normally. 1 Transmission has failed.

49.3.43 UART CEA709.1-B Status Register (UARTx_S4)

Address: Base address + 2Ch offset

Bit	7	6	5	4	3	2	1	0
Read	0			INITF	CDET		ILCV	FE
Write					w1c		w1c	w1c
Reset	0	0	0	0	0	0	0	0

UARTx_S4 field descriptions

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 INITF	Initial Synchronization Fail Flag Indicates that the initial synchronization has failed and the packet cycle time has expired after enabling EN709 register. This flag is cleared if EN709 is cleared. 0 Initial synchronization has not failed. 1 Initial synchronization has failed.
3–2 CDET	CDET

Table continues on the next page...

UARTx_S4 field descriptions (continued)

Field	Description
	Indicates when the collision occurs during transmission. This flag is cleared by writing 2'b11. If the collision flag is not cleared by software and a valid collision pulse is detected during some other phase of transmission, then collision flag continues to indicate the previous value. 00 No collision. 01 Collision occurred during preamble. 10 Collision occurred during byte sync or data. 11 Collision occurred during line code violation.
1 ILCV	Improper Line Code Violation Indicates that line code violation received is not proper. This flag is cleared by writing 1. 0 Line code violation received is proper. 1 Line code violation received is improper, that is, less than three bit periods.
0 FE	Framing Error Indicates that the received CEA709.1-B packet has not finished at a byte boundary. This flag is cleared by writing 1. 0 Received packet is byte aligned. 1 Received packet is not byte aligned.

49.3.44 UART CEA709.1-B Received Packet Length (UARTx_RPL)

Address: Base address + 2Dh offset

Bit	7	6	5	4	3	2	1	0
Read	RPL							
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_RPL field descriptions

Field	Description
7–0 RPL	Received Packet Length Indicates the length of received packet in bytes. If the received packet is not byte aligned, the partial byte received is appended by zeros.

49.3.45 UART CEA709.1-B Received Preamble Length (UARTx_RPREL)

Address: Base address + 2Eh offset

Bit	7	6	5	4	3	2	1	0
Read	RPREL							
Write								
Reset	0	0	0	0	0	0	0	0

UARTx_RPREL field descriptions

Field	Description
7–0 RPREL	Received Preamble Length Indicates the number of bit sync fields received in the preamble. The length saturates to 255 for the cases where the preamble (bit sync) is larger than 255. **NOTE:** The preamble length counter resets whenever there is no edge transition (SSSSS or DDDDD) during the resynchronization phase of preamble detection.

49.3.46 UART CEA709.1-B Collision Pulse Width (UARTx_CPW)

Address: Base address + 2Fh offset

Bit	7	6	5	4	3	2	1	0
Read Write	CPW							
Reset	0	0	0	0	0	0	0	0

UARTx_CPW field descriptions

Field	Description
7–0 CPW	CEA709.1-B CPW register Indicates the width of valid collision pulse in terms of IPG clock cycles.

49.3.47 UART CEA709.1-B Receive Indeterminate Time (UARTx_RIDT)

Address: Base address + 30h offset

Bit	7	6	5	4	3	2	1	0
Read Write	RIDT							
Reset	0	0	0	0	0	0	0	0

UARTx_RIDT field descriptions

Field	Description
7–0 RIDT	CEA709.1-B Receive IDT register Indicates the indeterminate time period measured in bit times after reception during which any activity on RX line will be discarded. Indeterminate time period value should be less than Beta1 timer value.

49.3.48 UART CEA709.1-B Transmit Indeterminate Time (UARTx_TIDT)

Address: Base address + 31h offset

Bit	7	6	5	4	3	2	1	0
Read Write	TIDT							
Reset	0	0	0	0	0	0	0	0

UARTx_TIDT field descriptions

Field	Description
7–0 TIDT	CEA709.1-B Transmit IDT Register This register indicates the indeterminate time period measured in bit times after transmission during which any activity on TX line will be discarded. Indeterminate time period value should be less than Beta1 timer value.

49.4 Functional description

This section provides a complete functional description of the UART block.

The UART allows full duplex, asynchronous, NRZ serial communication between the CPU and remote devices, including other CPUs. The UART transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the UART, writes the data to be transmitted, and processes received data.

49.4.1 CEA709.1-B

The UART provides support for CEA709.1-B, which is commonly used in building automation, home networking, including all key building automation subsystems such as heating, ventilating, air-conditioning, lighting, security, fire detection, access control, and energy monitoring.

49.4.1.1 CEA709.1-B packet cycle

The following figure illustrates the frame format and Differential Manchester encoding. Differential Manchester encoding requires that each transmitted bit includes a clock transition at the start of the bit period. This allows synchronization with the receiver.

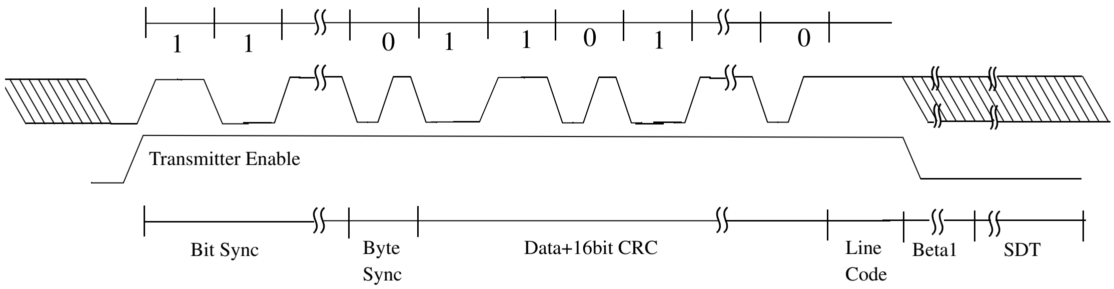

Figure 49-337. Frame format with differential manchester encoding

A logic zero is indicated with the presence of a transition in the middle of the bit period and a logic one is indicated by the absence of any transition. When transitions occur at the start of the bit time, polarity is arbitrary because the last bit of a transmission has no trailing clock edge. A transmitter will transmit a preamble at the beginning of a packet to allow other nodes to synchronize their receiver clocks. The preamble comprises a bit-sync field followed by a byte-sync field. The bit-sync field is a series of differential Manchester logic ones and the byte-sync field is a single differential Manchester logic zero. The byte-sync field marks the end of the preamble and the start of the data field (MPDU/LPDU).

The transmitter terminates the packet by forcing the data output to be transitionless long enough for the receiver to recognize an invalid bit code. This signals the end of the packet. At the end of the packet transmission, the line must remain transitionless for three bit periods after the final clock transition.

The UART is responsible for providing the BitSync and ByteSync fields of the PPDU illustrated below. The layer two software manages all other encapsulating fields and provides these to the UART as part of the packet to be transmitted.

Bit Sync	Byte Sync	Priority	Alt Path	Delta BL	NPDU	CRC

Figure 49-338. Physical protocol data unit structure

NOTE

The maximum possible delay between the transmission of 3T line code violation from the end of final data bit and start of TB1T and TIDT timer is one sample clock.

49.4.1.2 Packet cycle and delay calculations

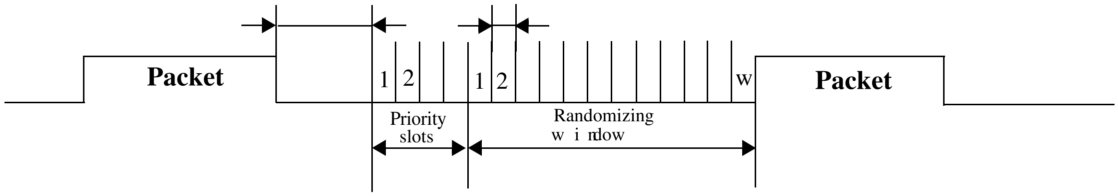

Figure 49-339. CEA709.1-B packet cycle

Predictive p-persistent CSMA is a technique for collision avoidance that randomizes channel access using knowledge of predicted load. It manages software using data and events reported by the hardware.

Beta1 delay is a value set by the software. It is generally a fixed value that is system dependent and hence does not usually require adjustment. It is measured in bit times, that is, the time that it takes for a single bit to be transmitted or one differential Manchester symbol. Beta1 is defined by CEA/EIA-709 specification as:

Beta1 > 1 bit time + $(2 \times T_{aup} + T_{aum})$

Where T_{aup} is the physical propagation delay defined by the media length.

T_{aum} is the detection and turn around-delay within the MAC sublayer; this is the period from the time the idle channel condition is detected, to the point when the first output transition appears on the output. On media where there is a carrier, this time must include the time between turning on the carrier, and it being asserted as a valid carrier on the medium.

The secondary delay timer is a value that is set by software. This is generally a variable value that must be set for each data message to be transmitted. It is measured in bit times, that is, the time that it takes for a single bit to be transmitted or one differential Manchester symbol. This value must be between 0 and (BL × Wbase) + (ProritySlots -1), Beta2 timeslots. A value of zero indicates that the queued packet for transmit is to be sent immediately upon expiration of the beta1 timer. According to the CEA/EIA-709 specification:

- BL is back log
- Wbase is 16 beta2 timeslots
- A priorityslot is the same amount of time as a beta2 timeslot
- Beta2 > $2 \times T_{aup} + T_{aum}$

Priority slots are handled completely by software. When calculating the secondary delay timer value, the software must take into account any priority slot that is included in the design of the system.

Each node must maintain an estimation of the current channel backlog. Backlog calculation is managed by the layer two software. Initially, the backlog is set to one. The backlog is incremented on transmission by a value indicated in the frames backlog increment field.

The backlog decrements under the following conditions:

- On waiting to transmit: If Wbase randomizing slots go by without channel activity.
- On receive: If a packet is received with a backlog increment of 0.
- On transmit: If a packet is transmitted with a backlog increment of 0.
- On idle: If a packet cycle time expires without channel activity.

The following actions need to be completed when a frame is received to prepare an outgoing message for transmission after the channel becomes idle:

- CRC of incoming message needs to be verified by software.
- If the CRC is good, the BL is recalculated, otherwise BL remains the same.
- Transmit delay (secondary delay timer) is calculated and supplied to UART.

49.4.1.3 Clock resynchronization

The UART is transmitting on time base source. Therefore, all receivers keep synchronizing with the node that is transmitting and no clock resynchronization occurs in transmitting.

When the UART is receiving or waiting to transmit, clock resynchronization is vital. Because long streams of data are possible (up to 229 bytes + headers), there exists significant potential for nodes to wander regarding time reference over the course of the message. Therefore, Differential Manchester Encoding (DME) is used. While DME requires twice the bandwidth of non-return to zero (NRZ) encoding schemes, it has the benefit of a guaranteed transition at the start of each bit transmitter. A transition occurring at the middle of the bit is encoded as a logic 0 or the lack of a transition at the middle of the bit time is encoded as a logic 1. By detecting the transition at the start of a bit period, the receiver is able to be resynthesized to the transmitter every bit period. Resynchronization can occur only after the node is already synchronized with the system. Additionally, for resynchronization to be effective, some basic assumptions regarding the system must be made:

1. Only a single channel sample may be in error (noise) over the entire bit (16 samples) period.
2. While a node is drifted from the system time base, with the resynchronization, the node is never shifted by more than 2 data samples in a given bit period.
3. If multiple noise events have occurred, no action is taken.

4. If a single noise event occurs, and it is possible to uniquely identify the noise event, then resynchronization takes place.

Starting at sample 15 of the previous time bit period, five data samples are collected. The number and location of the samples are key to decide if an adjustment in time base is required. Table below lists the possible values and the actions associated with each possibility. In the table, S means the data is the same as the logical value that was received in the second half of the previous bit period. D means that the sample is different from the logical value that was received in the second half of the previous bit period.

Sample Values (15,16,1,2,3)	Action / Event
SSSSS	No start of bit transition has been detected. Hence no adjustment to time base is made.
SSSSD	Two or more error events occurred or the time base was off. In this case, the time base is slowed down by two. Sample 3 becomes sample 1. The next sample is treated as sample 2.
SSSDS	Either two (or more) error events occurred, time base were off along with noise occurrence or sample 2 is noise and there is no start of bit transition. Hence no adjustment to time base is made.
SSSDD	It is possible that either noise was received during sample 1 or the time base needs shifting. In this case, the time base is slowed down by one. Sample 2 becomes sample 1, and sample 3 becomes sample 2. The next sample is treated as sample 3.
SSDSS	It is most likely that sample 1 is noise and there is no start of bit transition. Hence no adjustment to time base is made.
SSDSD	It is possible that sample 1 is noise, and time base needs shifting by two, or that sample 2 is noise. It is more likely that sample 2 is noise and therefore no adjustment to time base is made.
SSDDS	It is most likely that sample 3 is noise. Therefore, no adjustment to time base is made.
SSDDD	This is the expected case. Therefore, no adjustment to time base is made.
SDSSS	It is most likely that sample 16 is noise and there is no start of bit transition, hence no adjustment to time base is made.
SDSSD	Either multiple errors occurred or sample 16 is noise and time base is off by two. In this case, the time base is slowed down by two. Sample 3 becomes sample 1. The next sample is treated as sample 2.
SDSDS	In this case multiple errors have occurred. Hence no adjustment to time base is made.
SDSDD	In this case, there must either be multiple noise or one noise (at sample 16 or sample 1) with a time shift. Assuming that one noise occurred, it unclear what direction the time shift is. Hence no adjustment to time base is made.

Table continues on the next page...

Sample Values (15,16,1,2,3)	Action / Event
SDDSS	In this case either multiple errors occurred, two (or more) noise or two (or more) noise and a time shift. The most likely case is that samples 16 and 1 are noise. Hence no adjustment to time base is made.
SDDSD	The most likely case is noise for sample 2 and a time shift. Therefore, the time base is sped up by one. Sample 16 becomes sample 1, sample 1 becomes sample 2, sample 2 becomes sample 3, sample 3 becomes sample 4, and the next sample taken is sample 5.
SDDDS	The most likely case is noise for sample 3 and a time shift. Therefore, the time base is sped up by one. Sample 16 becomes sample 1, sample 1 becomes sample 2, sample 2 becomes sample 3, sample 3 becomes sample 4, and the next sample taken is sample 5.
SDDDD	Either sample 16 is noise or the time base has shifted. In this case, it is assumed that a time shift has occurred. Therefore, the time base is sped up by one. Sample 15 becomes sample 1, sample 1 becomes sample 2, sample 2 becomes sample 3, sample 3 becomes sample 4, and the next sample taken is sample 5.
DSSSS	It is most likely that sample 16 is noise and there is no start of bit transition, hence no adjustment to time base is made.
DSSSD	It is most likely that sample 15 is noise along with time shift. In this case, the time base is slowed down by two. Sample 3 becomes sample 1. The next sample is treated as sample 2.
DSSDS	In this case multiple errors occurred. Hence no adjustment to time base is made.
DSSDD	Either multiple errors occurred, possibly with time shift, or sample 15 is noise. In this case, the time base is slowed down by one. Sample 2 becomes sample 1, and sample 3 becomes sample 2. The next sample is treated as sample 3.
DSDSS	In this case multiple errors occurred. Hence no adjustment to time base is made.
DSDSD	In this case, multiple errors occurred. Therefore, no adjustment to time base is made.
DSDDS	In this case, multiple errors occurred. Therefore, no adjustment to time base is made.
DSDDD	In this case, either multiple errors occurred or sample 15 is noise and there is no start of bit transition. Therefore, no adjustment to time base is made.
DDSSS	In this case multiple errors occurred. It is most likely that samples 15 and 16 are noise. Hence no adjustment to time base is made.
DDSSD	In this case multiple errors occurred. Hence no adjustment to time base is made.
DDSDS	In this case multiple errors occurred. Hence no adjustment to time base is made.

Table continues on the next page...

Sample Values (15,16,1,2,3)	Action / Event
DDSDD	It is most likely that sample 1 is noise. Therefore, the time base is sped up by two. Sample 15 becomes sample 1, sample 16 becomes sample 2, sample 1 becomes sample 3, sample 2 becomes sample 4, sample 3 becomes sample 5, and the next sample taken is sample 6.
DDDSS	In this case multiple errors occurred along with time shift. Hence no adjustment to time base is made.
DDDSD	It is most likely that sample 2 is noise. Therefore, the time base is sped up by two. Sample 15 becomes sample 1, sample 16 becomes sample 2, sample 1 becomes sample 3, sample 2 becomes sample 4, sample 3 becomes sample 5, and the next sample taken is sample 6.
DDDDS	It is most likely that sample 3 is noise. Therefore, the time base is sped up by two. Sample 15 becomes sample 1, sample 16 becomes sample 2, sample 1 becomes sample 3, sample 2 becomes sample 4, sample 3 becomes sample 5, and the next sample taken is sample 6.
DDDDD	Either samples 15 and 16 are noise or the time base has shifted. Therefore, the time base is speed up by two. Sample 15 becomes sample 1, sample 16 becomes sample 2, sample 1 becomes sample 3, sample 2 becomes sample 4, sample 3 becomes sample 5, and the next sample taken is sample 6.

49.4.1.4 Data sampling

The receiver samples the unsynchronized receiver input signal at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock is resynchronized after every bit.

To locate the start of preamble, data recovery logic does an asynchronous search for a valid edge, logic 0 preceded by two logic 1s or logic 1 preceded by two logic 0s. When the falling edge or rising edge of a possible preamble bit occurs, the RT clock begins to count to 16.

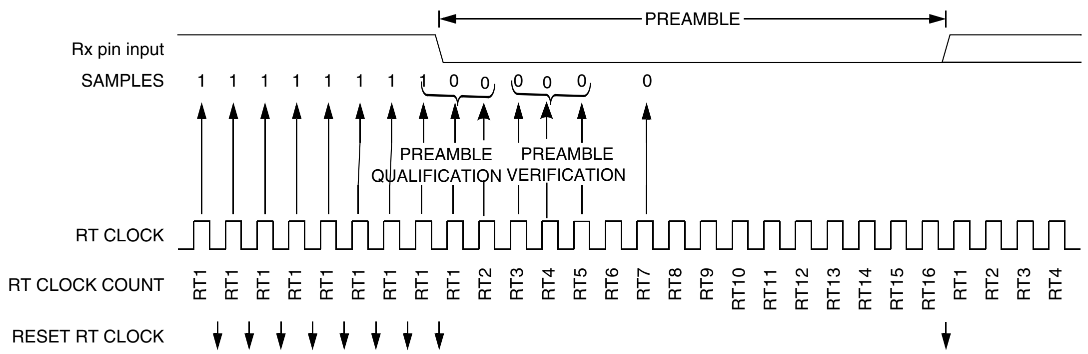

Figure 49-340. Receiver data sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT4, and RT5. The following table summarizes the results of the preamble verification samples.

Table 49-347. Preamble/ Data bit verification

RT3, RT4, and RT5 samples	Preamble verification
000	Yes
001	Yes
010	Yes
011	No
100	Yes
101	No
110	No
111	No

If preamble verification is not successful, the RT clock is reset and a new search for a preamble begins.

To determine the value of a data bit, recovery logic takes samples at RT11, RT12, and RT13. The following table summarizes the results of the data bit samples. If the majority of RT11, RT12, and RT13 samples is the same as the majority of RT3, RT4, and RT5 samples, then the data bit detected is 1, else the data bit detected is 0.

Table 49-348. Data bit recovery

RT11, RT12, and RT13 samples	Data bit determination
000	0
001	0
010	0
011	1
100	0
101	1
110	1
111	1

To signify the end of a data packet, the transmitter causes a line-code violation to occur, that is, the transmitter remains transitionless for at least 3-bit periods after the final clock transition, excluding the final data transition, if it exists. The receiver detects this violation. For the purpose of detecting a line-code violation, the receiver monitors the channel to locate a series of five or six back-to-back half bit periods.

49.4.1.5 Initial clock synchronization

When operating with EN709 set, there are various times when initial clock synchronization is required. When the UART has just been enabled, there is clearly no system clock reference. Additionally, if a channel has remained idle for a significant period of time, such as the arbitration time between packets, substantial clock drift may have occurred in the system between nodes. This is because there have been meaningful clock transitions on the channel to keep nodes synchronized. After these events, the clock may require significant synchronization adjustment; this event is referred to as initial clock synchronization.

There are three situations that may occur when a node attempts to obtain initial clock synchronization.

1. The node enters the system while a data packet is being actively transmitted.
2. The node enters the system while there is no data packet being actively transmitted on the system.
3. The node is already in the system and initial clock synchronization is required due to the end of a packet.

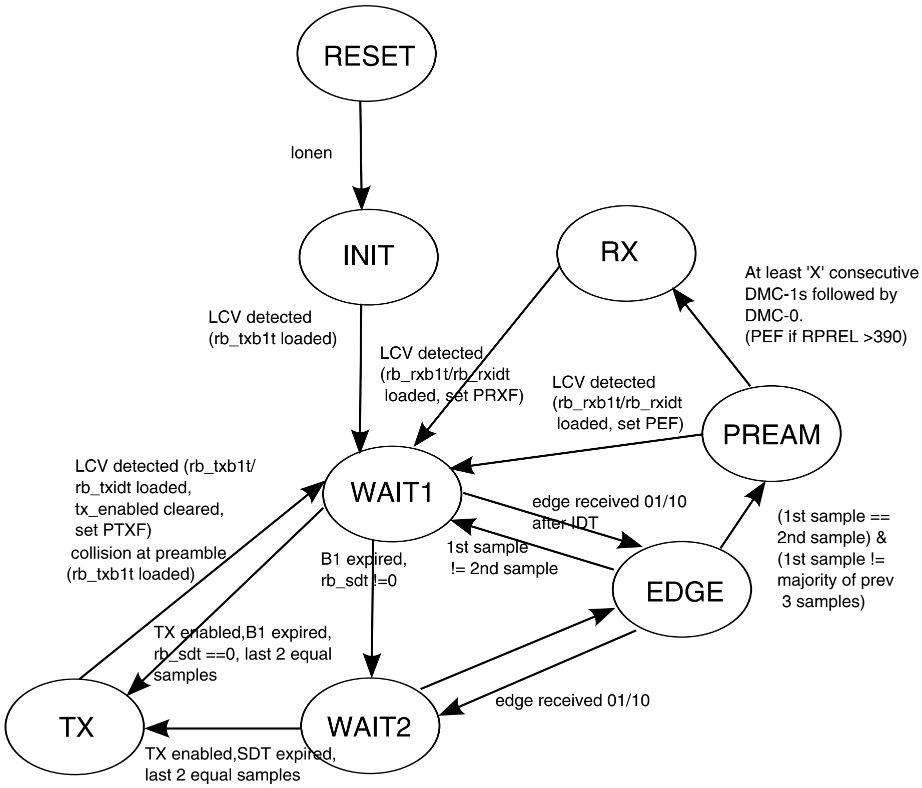
For case 1 and 2, the UART implements the following procedure:

1. The UART attempts to identify a valid line code violation. The line code violation is detected if the LCV counter reached the programmed value (default 20). The LCV counter resets automatically whenever valid edge is identified. Valid edge is identified if there is a transition in samples i.e. 0->1(sample1) or 1->0(sample1), and the subsequent two samples are equal (i.e sample 1 and sample 2) and sample 1 is not equal to the majority of previous 3 samples with respect to sample 1.
2. If the required line-code violation is detected, the beta1 delay timer will start and the UART will transit to case 3. Until then the UART will not be able to receive nor transmit any packet.

For case 3, it implements the following procedure:

1. Beta1 delay and secondary delay times increment as appropriate, that is Beta1 delay expires before the secondary delay timer starts.
2. While the timers are counting, the UART attempts to identify a valid edge.
3. If a valid receive edge is identified after the appropriate IDT has expired (RIDT or TIDT), but before the SDT expires and data is queued to be transmitted (C6[TX709] set), the transmission will be aborted before starting and the incoming data packet will be received. The S3[TXFF] flag will set to indicate that the transmission did not start.

4. If a valid edge is not identified before the delay time expires, and data is queued to be transmitted, the UART considers itself synchronized, and starts the preamble process.
5. If a valid edge is not identified before the delay time expires, and data is not queued to be transmitted, the UART continues attempting to locate a valid edge using the same process, and receives the incoming data packet like in step 3.



49.4.1.6 Priority packet preemption

The first data is fetched from the data buffer immediately after the preamble has completed. Therefore, it is possible to decide which data is sent during transmission until the completion of the preamble. This can be done in two different ways.

- The expected data to be transmitted can be written to the data buffer before or shortly after TE is enabled. In this case, the data is ready before the start of the preamble period. If a high priority packet has been identified for immediate/preemptive transmission, software may flush the data buffer and put the new data into the data buffer. This new data must be put into the data buffer prior to the completion of the preamble. Similarly, the transmit packet length register needs to be updated.
- Software can trigger data to be transmitted by asserting TE before the actual data has been placed in the data buffer. In the end, the software can write data into the data

buffer and update the transmit packet length register. This occurs before the preamble completes. To assist in identifying how much time is left before the preamble completes, the preamble started interrupt is asserted when the UART starts transmitting the preamble.

NOTE

1. If the data buffer does not contain at least one byte of valid data and the transmit packet length register has been updated prior to the preamble completing, an underflow event will occur and TXEN is deasserted. The packet is terminated by transmitting line code violation.
2. The maximum possible delay between masking the RX (due to LON FSM entering into TX State) and the first transmit preamble edge is 1 bit time while OBE is asserted with no delay with respect to masking of RX line.

49.4.1.7 Collision detection

Collision flag is detected only when device is transmitting if C6[CE] is asserted. The collision pulse is valid if it is asserted for CPW number of peripheral clock cycles. If the collision signal is already asserted before the start of packet transmission, then the width of the collision pulse is calculated from the start of transmit packet as shown in the figure below. If the collision signal is not cleared by the software by writing 11b, then the flag continues to retain the previous value. After the flag is cleared, the collision pulse width is calculated again, and the flag is asserted, if the width is equal to or more than the programmed CPW value.

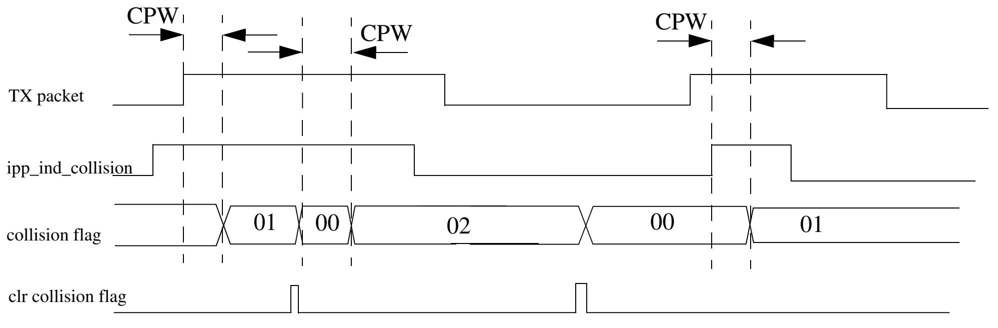


Figure 49-341. Collision pulse detection

The collision signal is asynchronous to the ipg clk, therefore the collision pulse of width exactly equal to CPW may not be detected correctly due to synchronization issue. The collision pulse visible to design may be decreased by one peripheral clock cycle due to the asynchronous nature of the collision pulse.

49.4.2 Transmitter

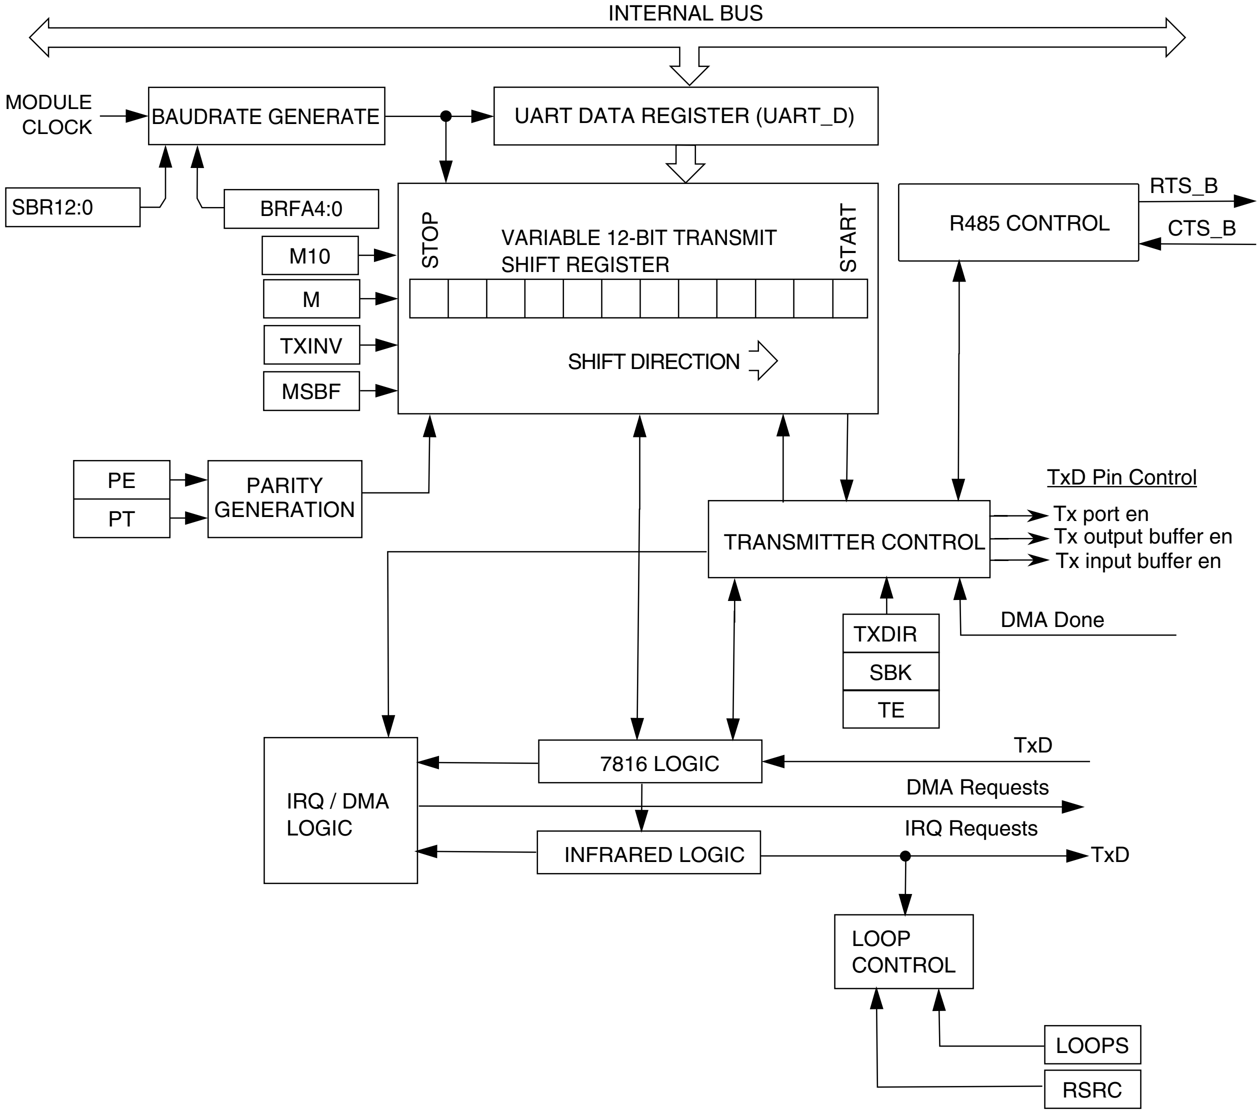

Figure 49-342. Transmitter Block Diagram

49.4.2.1 Transmitter character length

The UART transmitter can accommodate either 8, 9, or 10-bit data characters. The state of the C1[M] and C1[PE] bits and the C4[M10] bit determine the length of data characters. When transmitting 9-bit data, bit C3[T8] is the ninth bit (bit 8).

49.4.2.2 Transmission bit order

When S2[MSBF] is set, the UART automatically transmits the MSB of the data word as the first bit after the start bit. Similarly, the LSB of the data word is transmitted immediately preceding the parity bit, or the stop bit if parity is not enabled. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data written to D for transmission is completely independent of the S2[MSBF] setting.

49.4.2.3 Character transmission

To transmit data, the MCU writes the data bits to the UART transmit buffer using UART data registers C3[T8] and D. Data in the transmit buffer is then transferred to the transmitter shift register as needed. The transmit shift register then shifts a frame out through the transmit data output signal after it has prefaced it with any required start and stop bits. The UART data registers, C3[T8] and D, provide access to the transmit buffer structure.

The UART also sets a flag, the transmit data register empty flag S1[TDRE], and generates an interrupt or DMA request (C5[TDMAS]) whenever the number of datawords in the transmit buffer is equal to or less than the value indicated by TWFIFO[TXWATER]. The transmit driver routine may respond to this flag by writing additional datawords to the transmit buffer using C3[T8]/D as space permits.

See Application information for specific programing sequences.

Setting C2[TE] automatically loads the transmit shift register with the following preamble:

- 10 logic 1s if C1[M] = 0
- 11 logic 1s if C1[M] = 1 and C4[M10] = 0
- 12 logic 1s if C1[M] = 1, C4[M10] = 1, C1[PE] = 1

After the preamble shifts out, control logic transfers the data from the D register into the transmit shift register. The transmitter automatically transmits the correct start bit and stop bit before and after the dataword.

When C7816[ISO_7816E] = 1, setting C2[TE] does not result in a preamble being generated. The transmitter starts transmitting as soon as the corresponding guard time expires. When C7816[TTYPE] = 0, the value in GT is used. When C7816[TTYPE] = 1, the value in BGT is used, because C2[TE] will remain asserted until the end of the block transfer. C2[TE] is automatically cleared when C7816[TTYPE] = 1 and the block being transmitted has completed. When C7816[TTYPE] = 0, the transmitter listens for a NACK indication. If no NACK is received, it is assumed that the character was correctly

received. If a NACK is received, the transmitter resends the data, assuming that the number of retries for that character, that is, the number of NACKs received, is less than or equal to the value in ET7816[TXTHRESHOLD].

Hardware supports odd or even parity. When parity is enabled, the bit immediately preceding the stop bit is the parity bit.

When the transmit shift register is not transmitting a frame, the transmit data output signal goes to the idle condition, logic 1. If at any time software clears C2[TE], the transmitter enable signal goes low and the transmit signal goes idle.

If the software clears C2[TE] while a transmission is in progress, the character in the transmit shift register continues to shift out, provided S1[TC] was cleared during the data write sequence. To clear S1[TC], the S1 register must be read followed by a write to D register.

If S1[TC] is cleared during character transmission and C2[TE] is cleared, the transmission enable signal is deasserted at the completion of the current frame. Following this, the transmit data out signal enters the idle state even if there is data pending in the UART transmit data buffer. To ensure that all the data written in the FIFO is transmitted on the link before clearing C2[TE], wait for S1[TC] to set. Alternatively, the same can be achieved by setting TWFIFO[TXWATER] to 0x0 and waiting for S1[TDRE] to set.

49.4.2.4 Transmitting break characters

Setting C2[SBK] loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on C1[M], C1[PE], S2[BRK13] and C4[M10]. See the following table.

Table 49-349. Transmit break character length

S2[BRK13]	C1[M]	C4[M10]	C1[PE]	Bits transmitted
0	0	—	—	10
0	1	1	0	11
0	1	1	1	12
1	0	—	—	13
1	1	—	—	14

As long as C2[SBK] is set, the transmitter logic continuously loads break characters into the transmit shift register. After the software clears C2[SBK], the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next character. Break bits are not supported when C7816[ISO_7816E] is set/enabled.

NOTE

When queuing a break character, it will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that, if data is queued in the data buffer to be transmitted, the break character preempts that queued data. The queued data is then transmitted after the break character is complete.

49.4.2.5 Idle characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on C1[M], C1[PE] and C4[M10]. The preamble is a synchronizing idle character that begins the first transmission initiated after setting C2[TE]. When C7816[ISO_7816E] is set/enabled, idle characters are not sent or detected. When data is not being transmitted, the data I/O line is in an inactive state.

If C2[TE] is cleared during a transmission, the transmit data output signal becomes idle after completion of the transmission in progress. Clearing and then setting C2[TE] during a transmission queues an idle character to be sent after the dataword currently being transmitted.

Note

When queuing an idle character, the idle character will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that if data is queued in the data buffer to be transmitted, the idle character preempts that queued data. The queued data is then transmitted after the idle character is complete.

If C2[TE] is cleared and the transmission is completed, the UART is not the master of the TXD pin.

49.4.2.6 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS. If the clear-to-send operation is enabled, the character is transmitted when CTS is asserted. If CTS is deasserted in the middle of a transmission with characters remaining in the receiver data buffer, the character in the shift register is sent and TXD remains in the mark state until CTS is reasserted.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS. Also, if the transmitter is forced to send a continuous low condition because it is sending a break character, the transmitter ignores the state of CTS regardless of whether the clear-to-send operation is enabled.

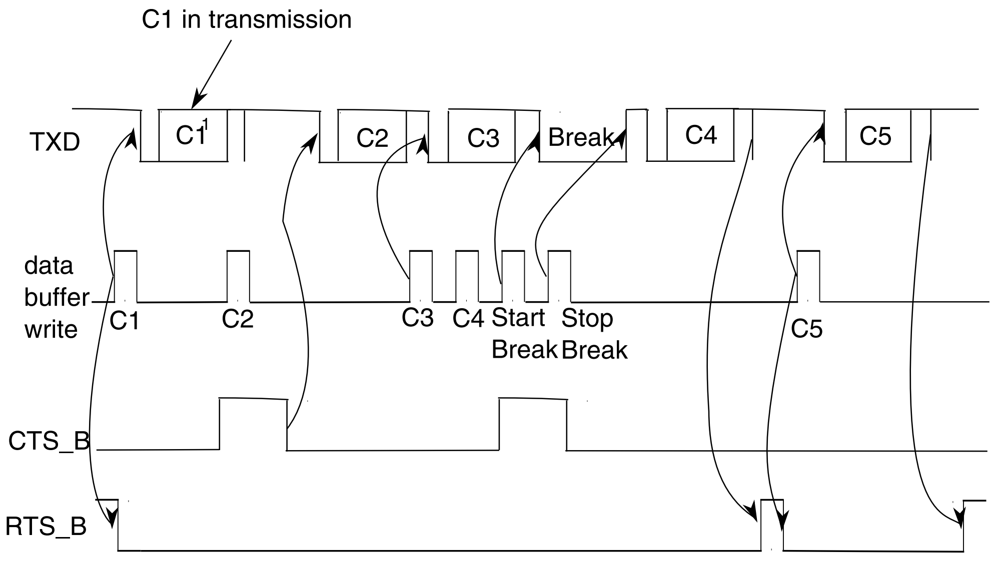
The transmitter's CTS signal can also be enabled even if the same UART receiver's RTS signal is disabled.

49.4.2.7 Transceiver driver enable

The transmitter can use RTS as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, RTS asserts one bit time before the start bit is transmitted. RTS remains asserted for the whole time that the transmitter data buffer has any characters. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts RTS, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's RTS signal asserts only when the transmitter is enabled. However, the transmitter's RTS signal is unaffected by its CTS signal. RTS will remain asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

The following figure shows the functional timing information for the transmitter. Along with the actual character itself, TXD shows the start bit. The stop bit is also indicated, with a dashed line if necessary.



1. Cn = transmit characters

Figure 49-343. Transmitter RTS and CTS timing diagram

49.4.3 Receiver

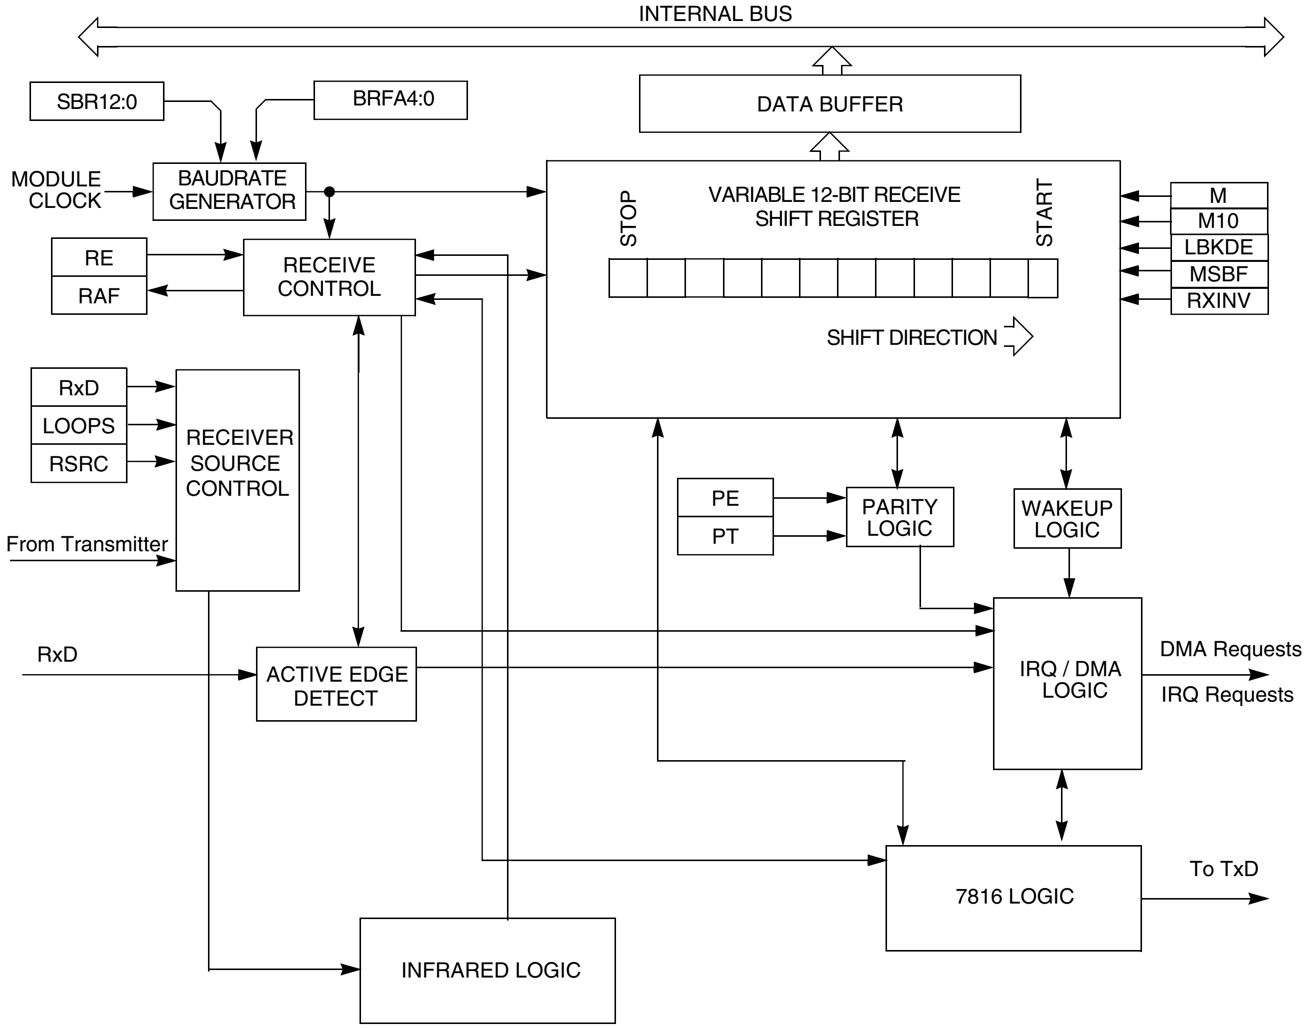


Figure 49-344. UART receiver block diagram

49.4.3.1 Receiver character length

The UART receiver can accommodate 8-, 9-, or 10-bit data characters. The states of C1[M], C1[PE] and C4[M10] determine the length of data characters. When receiving 9 or 10-bit data, C3[R8] is the ninth bit (bit 8).

49.4.3.2 Receiver bit ordering

When S2[MSBF] is set, the receiver operates such that the first bit received after the start bit is the MSB of the dataword. Similarly, the bit received immediately preceding the parity bit, or the stop bit if parity is not enabled, is treated as the LSB for the dataword. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data read from receive data buffer is completely independent of S2[MSBF].

49.4.3.3 Character reception

During UART reception, the receive shift register shifts a frame in from the unsynchronized receiver input signal. After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the UART receive buffer. Additionally, the noise and parity error flags that are calculated during the receive process are also captured in the UART receive buffer. The receive data buffer is accessible via the D and C3[T8] registers. Additional received information flags regarding the receive dataword can be read in ED register. S1[RDRF] is set if the number of resulting datawords in the receive buffer is equal to or greater than the number indicated by RWFIFO[RXWATER]. If the C2[RIE] is also set, RDRF generates an RDRF interrupt request. Alternatively, by programming C5[RDMAS], a DMA request can be generated.

When C7816[ISO_7816E] is set/enabled and C7816[TTYPE] = 0, character reception operates slightly differently. Upon receipt of the parity bit, the validity of the parity bit is checked. If C7816[ANACK] is set and the parity check fails, or if INIT and the received character is not a valid initial character, then a NACK is sent by the receiver. If the number of consecutive receive errors exceeds the threshold set by ET7816[RXTHRESHOLD], then IS7816[RXT] is set and an interrupt generated if IE7816[RXTE] is set. If an error is detected due to parity or an invalid initial character, the data is not transferred from the receive shift register to the receive buffer. Instead, the data is overwritten by the next incoming data.

When the C7816[ISO_7816E] is set/enabled, C7816[ONACK] is set/enabled, and the received character results in the receive buffer overflowing, a NACK is issued by the receiver. Additionally, S1[OR] is set and an interrupt is issued if required, and the data in the shift register is discarded.

49.4.3.4 Framing errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag, S1[FE], if S2[LBKDE] is disabled. When S2[LBKDE] is disabled, a break character also sets the S1[FE] because a break character

has no stop bit. S1[FE] is set at the same time that received data is placed in the receive data buffer. Framing errors are not supported when C7816[ISO7816E] is set/enabled. However, if S1[FE] is set, data will not be received when C7816[ISO7816E] is set.

49.4.3.5 Receiving break characters

The UART recognizes a break character when a start bit is followed by eight, nine, or ten logic 0 data bits and a logic 0 where the stop bit should be. Receiving a break character has these effects on UART registers:

- Sets the framing error flag, S1[FE].
- Writes an all 0 dataword to the data buffer, which may cause S1[RDRF] to set, depending on the watermark and number of values in the data buffer.
- May set the overrun flag, S1[OR], noise flag, S1[NF], parity error flag, S1[PE], or the receiver active flag, S2[RAF].

The detection threshold for a break character can be adjusted when using an internal oscillator in a LIN system by setting S2[LBKDE]. The UART break character detection threshold depends on C1[M], C1[PE], S2[LBKDE] and C4[M10]. See the following table.

Table 49-350. Receive break character detection threshold

LBKDE	M	M10	PE	Threshold (bits)
0	0	—	—	10
0	1	0	—	11
0	1	1	1	12
1	0	—	—	11
1	1	—	—	12

While S2[LBKDE] is set, it will have these effects on the UART registers:

- Prevents S1[RDRF], S1[FE], S1[NF], and S1[PF] from being set. However, if they are already set, they will remain set.
- Sets the LIN break detect interrupt flag, S2[LBKDIF], if a LIN break character is received.

Break characters are not detected or supported when C7816[ISO_7816E] is set/enabled.

49.4.3.6 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS.

- RTS remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS if the number of characters in the receiver data register is equal to or greater than receiver data buffer's watermark, RWFIFO[RXWATER].
- The receiver asserts RTS when the number of characters in the receiver data register is less than the watermark. It is not affected if RDRF is asserted.
- Even if RTS is deasserted, the receiver continues to receive characters until the receiver data buffer is full or is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS remains deasserted.

The following figure shows receiver hardware flow control functional timing. Along with the actual character itself, RXD shows the start bit. The stop bit can also indicated, with a dashed line, if necessary. The watermark is set to 2.

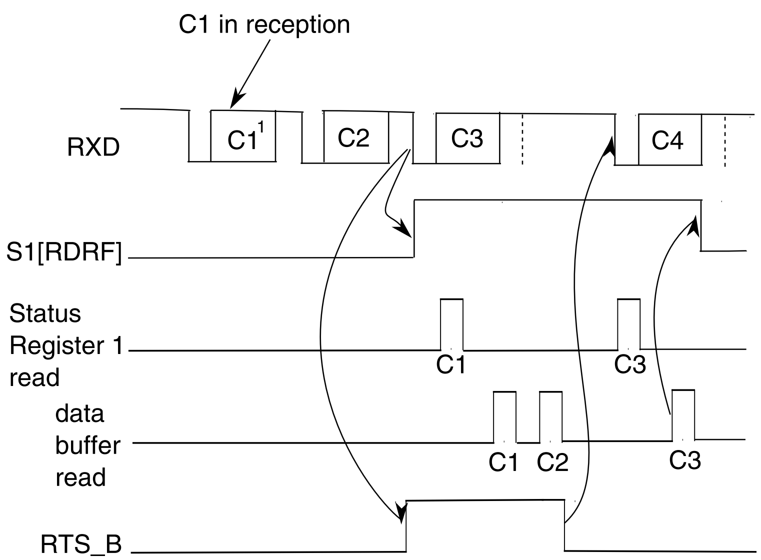

Figure 49-345. Receiver hardware flow control timing diagram

49.4.3.7 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a 16-RT clock counter that filters noise and indicates when a 1 is received.

49.4.3.7.1 Start bit detection

When S2[RXINV] is cleared, the first rising edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

49.4.3.7.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one RT clocks can be undetected by it regardless of whether it is seen in the first or second half of the count.

49.4.3.7.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

49.4.3.7.4 High-bit detection

At 16-RT clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

49.4.3.8 Baud rate tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error will occur if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic 0.

As the receiver samples an incoming frame, it resynchronizes the RT clock on any valid falling edge within the frame. Resynchronization within frames corrects a misalignment between transmitter bit times and receiver bit times.

49.4.3.8.1 Slow data tolerance

The following figure shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

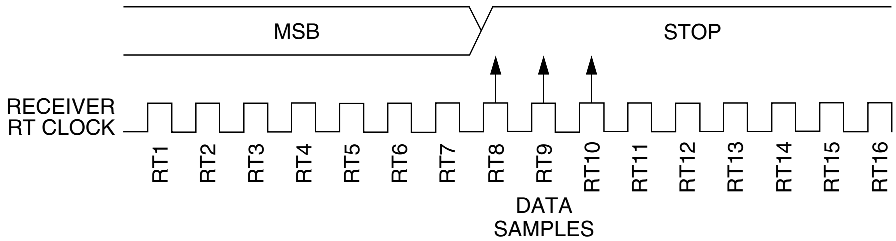

Figure 49-346. Slow data

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times × 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the Figure 49-346, the receiver counts 154 RT cycles at the point when the count of the transmitting device is 147 RT cycles (9 bit times × 16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

$$((154 - 147) \div 154) \times 100 = 4.54\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times × 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the Figure 49-346, the receiver counts 170 RT cycles at the point when the count of the transmitting device is 163 RT cycles (10 bit times × 16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

$$((170 - 163) \div 170) \times 100 = 4.12\%$$

49.4.3.8.2 Fast data tolerance

The following figure shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

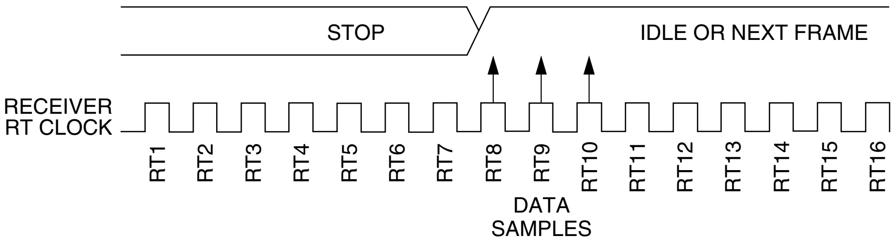

Figure 49-347. Fast data

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times × 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the Figure 49-347, the receiver counts 154 RT cycles at the point when the count of the transmitting device is 160 RT cycles (10 bit times × 16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

$$((154 - 160) \div 154) \times 100 = 3.90\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times × 16 RT cycles + 10 RT cycles).

With the misaligned character shown in the Figure 49-347, the receiver counts 170 RT cycles at the point when the count of the transmitting device is 176 RT cycles (11 bit times × 16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

$$((170 - 176) \div 170) \times 100 = 3.53\%$$

49.4.3.9 Receiver wakeup

C1[WAKE] determines how the UART is brought out of the standby state to process an incoming message. C1[WAKE] enables either idle line wakeup or address mark wakeup.

Receiver wakeup is not supported when C7816[ISO_7816E] is set/enabled because multi-receiver systems are not allowed.

49.4.3.9.1 Idle input line wakeup (C1[WAKE] = 0)

In this wakeup method, an idle condition on the unsynchronized receiver input signal clears C2[RWU] and wakes the UART. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another idle character appears on the unsynchronized receiver input signal.

Idle line wakeup requires that messages be separated by at least one idle character and that no message contains idle characters.

When C2[RWU] is 1 and S2[RWUID] is 0, the idle character that wakes the receiver does not set S1[IDLE] or the receive data register full flag, S1[RDRF]. The receiver wakes and waits for the first data character of the next message which is stored in the receive data buffer. When S2[RWUID] and C2[RWU] are set and C1[WAKE] is cleared, any idle condition sets S1[IDLE] and generates an interrupt if enabled.

Idle input line wakeup is not supported when C7816[ISO_7816E] is set/enabled.

49.4.3.9.2 Address mark wakeup (C1[WAKE] = 1)

In this wakeup method, a logic 1 in the bit position immediately preceding the stop bit of a frame clears C2[RWU] and wakes the UART. A logic 1 in the bit position immediately preceeding the stop bit marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another address frame appears on the unsynchronized receiver input signal.

A logic 1 in the bit position immediately preceding the stop bit clears the receiver's C2[RWU] after the stop bit is received and places the received data into the receiver data buffer. Note that if Match Address operation is enabled i.e. C4[MAEN1] or C4[MAEN2] is set, then received frame is transferred to receive buffer only if the comparison matches.

Address mark wakeup allows messages to contain idle characters but requires that the bit position immediately preceding the stop bit be reserved for use in address frames.

If module is in standby mode and nothing triggers to wake the UART, no error flag is set even if an invalid error condition is detected on the receiving data line.

Address mark wakeup is not supported when C7816[ISO_7816E] is set/enabled.

49.4.3.9.3 Match address operation

Match address operation is enabled when C4[MAEN1] or C4[MAEN2] is set. In this function, a frame received by the RX pin with a logic 1 in the bit position of the address mark is considered an address and is compared with the associated MA1 or MA2 register. The frame is transferred to the receive buffer, and S1[RDRF] is set, only if the comparison matches. All subsequent frames received with a logic 0 in the bit position of the address mark are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs, then no transfer is made to the receive data buffer, and all following frames with logic 0 in the bit position of the address mark are also discarded. If both C4[MAEN1] and C4[MAEN2] are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Match address operation functions in the same way for both MA1 and MA2 registers. Note that the position of the address mark is the same as the Parity Bit when parity is enabled for 8 bit and 9 bit data formats.

- If only one of C4[MAEN1] and C4[MAEN2] is asserted, a marked address is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If C4[MAEN1] and C4[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either register.

Address match operation is not supported when C7816[ISO_7816E] is set/enabled.

49.4.4 Baud rate generation

A 13-bit modulus counter and a 5-bit fractional fine-adjust counter in the baud rate generator derive the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to SBR[12:0] determines the module clock divisor. The SBR bits are in the UART baud rate registers, BDH and BDL. The baud rate clock is synchronized with the module clock and drives the receiver. The fractional fine-adjust counter adds fractional delays to the baud rate clock to allow fine trimming of the baud rate to match the system baud rate. The transmitter is driven by the baud rate clock divided by 16. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to two sources of error:

- Integer division of the module clock may not give the exact target frequency. This error can be reduced with the fine-adjust counter.
- Synchronization with the module clock can cause phase shift.

The Table 49-351 lists the available baud divisor fine adjust values.

UART baud rate = UART module clock / (16 × (SBR[12:0] + BRFD))

The following table lists some examples of achieving target baud rates with a module clock frequency of 10.2 MHz, with and without fractional fine adjustment.

Table 49-351. Baud rates (example: module clock = 10.2 MHz)

Bits SBR (decimal)	Bits BRFA	BRFD value	Receiver clock (Hz)	Transmitter clock (Hz)	Target Baud rate	Error (%)
17	00000	0	600,000.0	37,500.0	38,400	2.3
16	10011	19/32=0.59375	614,689.3	38,418.08	38,400	0.047
33	00000	0	309,090.9	19,318.2	19,200	0.62
33	00110	6/32=0.1875	307,344.6	19,209.04	19,200	0.047
66	00000	0	154,545.5	9659.1	9600	0.62
133	00000	0	76,691.7	4793.2	4800	0.14

49.4.5 Data format (non ISO-7816)

Each data character is contained in a frame that includes a start bit and a stop bit. The rest of the data format depends upon C1[M], C1[PE], S2[MSBF] and C4[M10].

49.4.5.1 Eight-bit configuration

Clearing C1[M] configures the UART for 8-bit data characters, that is, eight bits are memory mapped in D. A frame with eight data bits has a total of 10 bits. The most significant bit of the eight data bits can be used as an address mark to wake the receiver. If the most significant bit is used in this way, then it serves as an address or data indication, leaving the remaining seven bits as actual data. When C1[PE] is set, the eighth data bit is automatically calculated as the parity bit. See the following table.

Table 49-353. Configuration of 8-bit data format

UART_C1[PE]	Start bit	Data bits	Address bits	Parity bits	Stop bit
0	1	8	0	0	1

Table continues on the next page...

Table 49-353. Configuration of 8-bit data format (continued)

UART_C1[PE]	Start bit	Data bits	Address bits	Parity bits	Stop bit
0	1	7	1[1]	0	1
1	1	7	0	1	1

1. The address bit identifies the frame as an address character. See Receiver wakeup.

49.4.5.2 Nine-bit configuration

When C1[M] is set and C4[M10] is cleared, the UART is configured for 9-bit data characters. If C1[PE] is enabled, the ninth bit is either C3[T8/R8] or the internally generated parity bit. This results in a frame consisting of a total of 11 bits. In the event that the ninth data bit is selected to be C3[T8], it will remain unchanged after transmission and can be used repeatedly without rewriting it, unless the value needs to be changed. This feature may be useful when the ninth data bit is being used as an address mark.

When C1[M] and C4[M10] are set, the UART is configured for 9-bit data characters, but the frame consists of a total of 12 bits. The 12 bits include the start and stop bits, the 9 data character bits, and a tenth internal data bit. Note that if C4[M10] is set, C1[PE] must also be set. In this case, the tenth bit is the internally generated parity bit. The ninth bit can either be used as an address mark or a ninth data bit.

See the following table.

Table 49-354. Configuration of 9-bit data formats

C1[PE]	UC1[M]	C1[M10]	Start bit	Data bits	Address bits	Parity bits	Stop bit
0	0	0	See Eight-bit configuration				
0	0	1	Invalid configuration				
0	1	0	1	9	0	0	1
0	1	0	1	8	1[1]	0	1
0	1	1	Invalid Configuration				
1	0	0	See Eight-bit configuration				
1	0	1	Invalid Configuration				
1	1	0	1	8	0	1	1
1	1	1	1	9	0	1	1
1	1	1	1	8	1[2]	1	1

1. The address bit identifies the frame as an address character.
2. The address bit identifies the frame as an address character.

Note

Unless in 9-bit mode with M10 set, do not use address mark wakeup with parity enabled.

49.4.5.3 Timing examples

Timing examples of these configurations in the NRZ mark/space data format are illustrated in the following figures. The timing examples show all of the configurations in the following sub-sections along with the LSB and MSB first variations.

49.4.5.3.1 Eight-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

Figure 49-348. Eight bits of data with LSB first

49.4.6 Single-wire operation

Normally, the UART uses two pins for transmitting and receiving. In single wire operation, the RXD pin is disconnected from the UART and the UART implements a half-duplex serial connection. The UART uses the TXD pin for both receiving and transmitting.

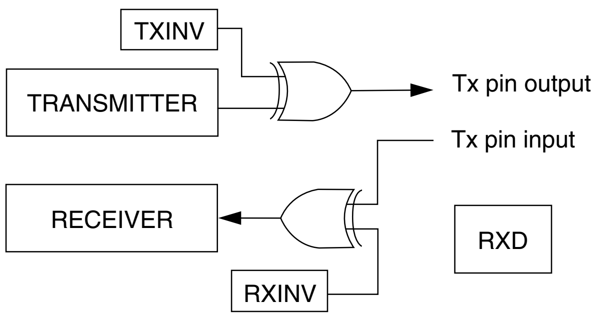

Figure 49-358. Single-wire operation (C1[LOOPS] = 1, C1[RSRC] = 1)

Enable single wire operation by setting C1[LOOPS] and the receiver source field, C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Setting C1[RSRC] connects the receiver input to the output of the TXD pin driver. Both the transmitter and receiver must be enabled (C2[TE] = 1 and C2[RE] = 1). When C7816[ISO_7816EN] is set, it is not required that both C2[TE] and C2[RE] are set.

49.4.7 Loop operation

In loop operation, the transmitter output goes to the receiver input. The unsynchronized receiver input signal is disconnected from the UART.

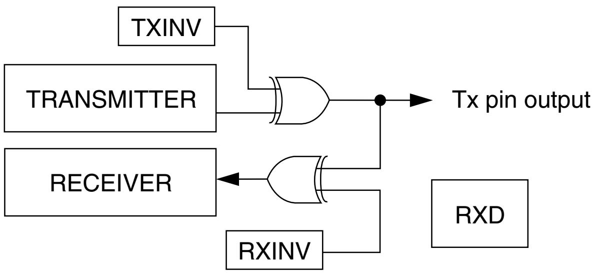

Figure 49-359. Loop operation (C1[LOOPS] = 1, C1[RSRC] = 0)

Enable loop operation by setting C1[LOOPS] and clearing C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Clearing C1[RSRC] connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled (C2[TE] = 1 and C2[RE] = 1). When C7816[ISO_7816EN] is set, it is not required that both C2[TE] and C2[RE] are set.

49.4.8 ISO-7816/smartcard support

The UART provides mechanisms to support the ISO-7816 protocol that is commonly used to interface with smartcards. The ISO-7816 protocol is an NRZ, single wire, half-duplex interface. The TxD pin is used in open-drain mode because the data signal is used for both transmitting and receiving. There are multiple subprotocols within the ISO-7816 standard. The UART supports both T = 0 and T = 1 protocols. The module also provides for automated initial character detection and configuration, which allows for support of both direct convention and inverse convention data formats. A variety of interrupts specific to 7816 are provided in addition to the general interrupts to assist software. Additionally, the module is able to provide automated NACK responses and has programmed automated retransmission of failed packets. An assortment of programmable timeouts and guard band times are also supported.

The term elemental time unit (ETU) is frequently used in the context of ISO-7816. This concept is used to relate the frequency that the system (UART) is running at and the frequency that data is being transmitted and received. One ETU represents the time it takes to transmit or receive a single bit. For example, a standard 7816 packet, excluding any guard time or NACK elements is 10 ETUs (start bit, 8 data bits, and a parity bit). Guard times and wait times are also measured in ETUs.,

NOTE

The ISO-7816 specification may have certain configuration options that are reserved. To maintain maximum flexibility to support future 7816 enhancements or devices that may not strictly conform to the specification, the UART does not prevent those options being used. Further, the UART may provide configuration options that exceed the flexibility of options explicitly allowed by the 7816 specification. Failure to correctly configure the UART may result in unexpected behavior or incompatibility with the ISO-7816 specification.

49.4.8.1 Initial characters

In ISO-7816 with T = 0 mode, the UART can be configured to use C7816[INIT] to detect the next valid initial character, referred to by the ISO-7816 specifically as a TS character. When the initial character is detected, the UART provides the host processor with an interrupt if IE7816[INITDE] is set. Additionally, the UART will alter S2[MSBF], C3[TXINV], and S2[RXINV] automatically, based on the initial character. The corresponding initial character and resulting register settings are listed in the following table.

Table 49-355. Initial character automated settings

Initial character (bit 1-10)	Initial character (hex)	MSBF	TXINV	RXINV
LHHL LLL LLH inverse convention	3F	1	1	1
LHHL HHH LLH direct convention	3B	0	0	0

S2[MSBF], C3[TXINV], and S2[RXINV] must be reset to their default values before C7816[INIT] is set. Once C7816[INIT] is set, the receiver searches all received data for the first valid initial character. Detecting a Direct Convention Initial Character will cause no change to S2[MSBF], C3[TXINV], and S2[RXINV], while detecting an Inverse Convention Initial Character will cause these fields to set automatically. All data

received, which is not a valid initial character, is ignored and all flags resulting from the invalid data are blocked from asserting. If C7816[ANACK] is set, a NACK is returned for invalid received initial characters and an RXT interrupt is generated as programmed.

49.4.8.2 Protocol T = 0

When T = 0 protocol is selected, a relatively complex error detection scheme is used. Data characters are formatted as illustrated in the following figure. This scheme is also used for answer to reset and Peripheral Pin Select (PPS) formats.

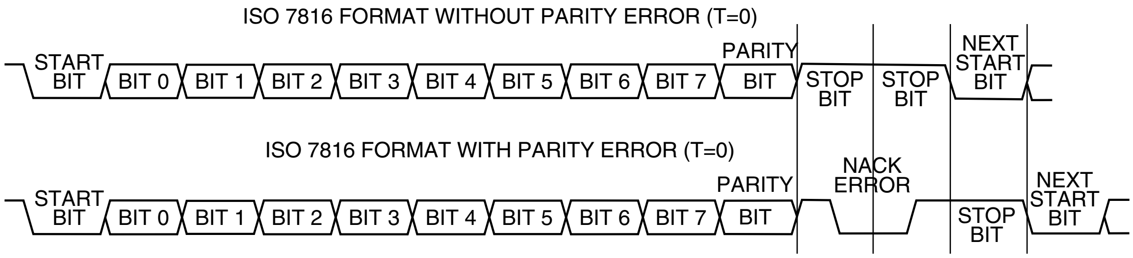

Figure 49-360. ISO-7816 T = 0 data format

As with other protocols supported by the UART, the data character includes a start bit. However, in this case, there are two stop bits rather than the typical single stop bit. In addition to a standard even parity check, the receiver has the ability to generate and return a NACK during the second half of the first stop bit period. The NACK must be at least one time period (ETU) in length and no more than two time periods (ETU) in length. The transmitter must wait for at least two time units (ETU) after detection of the error signal before attempting to retransmit the character.

It is assumed that the UART and the device (smartcard) know in advance which device is receiving and which is transmitting. No special mechanism is supplied by the UART to control receive and transmit in the mode other than C2[TE] and C2[RE]. Initial Character Detect feature is also supported in this mode.

49.4.8.3 Protocol T = 1

When T = 1 protocol is selected, the NACK error detection scheme is not used. Rather, the parity bit is used on a character basis and a CRC or LRC is used on the block basis, that is, for each group of characters. In this mode, the data format allows for a single stop bit although additional inactive bit periods may be present between the stop bit and the next start bit. Data characters are formatted as illustrated in the following figure.

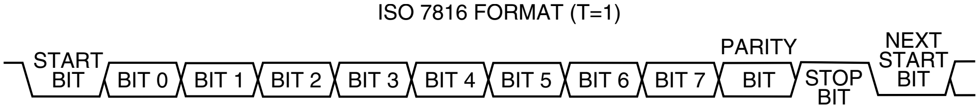

Figure 49-361. ISO 7816 T=1 data format

The smallest data unit that is transferred is a block. A block is made up of several data characters and may vary in size depending on the block type. The UART does not provide a mechanism to decode the block type. As part of the block, an LRC or CRC is included. The UART does not calculate the CRC or LRC for transmitted blocks, nor does it verify the validity of the CRC or LRC for received blocks. The 7816 protocol requires that the initiator and the smartcard (device) takes alternate turns in transmitting and receiving blocks. When the UART detects that the last character in a block has been transmitted it will automatically clear C2[TE], C3[TXDIR] and enter receive mode. Therefore, the software must program the transmit buffer with the next data to be transmitted and then enable C2[TE] and set C3[TXDIR], once the software has determined that the last character of the received block has been received. The UART detects that the last character of the transmit block has been sent when TL7816[TLEN] = 0 and four additional characters have been sent. The four additional characters are made up of three prior to TL7816[TLEN] decrementing (prologue) and one after TL7816[TLEN] = 0, the final character of the epilogue.

49.4.8.4 Wait time and guard time parameters

The ISO-7816 specification defines several wait time and guard time parameters. The UART allows for flexible configuration and violation detection of these settings. On reset, the wait time (IS7816[WT]) defaults to 9600 ETUs and guard time (GT) to 12 ETUs. These values are controlled by parameters in the WP7816, WN7816, and WF7816 registers. Additionally, the value of C7816[TTYPE] also factors into the calculation. The formulae used to calculate the number ETUs for each wait time and guard time value are shown in Table 49-356.

Wait time (WT) is defined as the maximum allowable time between the leading edge of a character transmitted by the smartcard device and the leading edge of the previous character that was transmitted by the UART or the device. Similarly, character wait time (CWT) is defined as the maximum allowable time between the leading edge of two characters within the same block. Block wait time (BWT) is defined as the maximum time between the leading edge character of the last block received by the smartcard device and the leading edge of the first character transmitted by the smartcard device.

Guard time (GT) is defined as the minimum allowable time between the leading edge of two consecutive characters. Character guard time (CGT) is the minimum allowable time between the leading edges of two consecutive characters in the same direction, that is,

transmission or reception. Block guard time (BGT) is the minimum allowable time between the leading edges of two consecutive characters in opposite directions, that is, transmission then reception or reception then transmission.

The GT and WT counters reset whenever C7816[TTYPE] = 1 or C7816[ISO_7816E] = 0 or a new dataword start bit has been received or transmitted as specified by the counter descriptions. The CWT, CGT, BWT, BGT counters reset whenever C7816[TTYPE] = 0 or C7816[ISO_7816E] = 0 or a new dataword start bit is received or transmitted as specified by the counter descriptions. When C7816[TTYPE] = 1, some of the counter values require an assumption regarding the first data transferred when the UART first starts. This assumption is required when the 7816E is disabled, when transition from C7816[TTYPE] = 0 to C7816[TTYPE] = 1 or when coming out of reset. In this case, it is assumed that the previous non-existent transfer was a received transfer.

The UART will automatically handle GT, CGT, and BGT such that the UART will not send a packet before the corresponding guard time expiring.

Table 49-356. Wait and guard time calculations

Parameter	Reset value [ETU]	C7816[TTYPE] = 0 [ETU]	C7816[TTYPE] = 1 [ETU]
Wait time (WT)	9600	$((WI + 1) \times 960 \times (GTFD + 1)) - 1$	Not used
Character wait time (CWT)	Not used	Not used	$11 + 2^{(CWI - 1)}$
Block wait time (BWT)	Not used	Not used	$10 + 2^{BWI} \times 960 \times (GTFD + 1)$
Guard time (GT)	12	**GTN not equal to 255** 12 + GTN **GTN equal to 255** 12	Not used
Character guard time (CGT)	Not used	Not used	**GTN not equal to 255** 12 + GTN **GTN equal to 255** 11
Block guard time (BGT)	Not used	Not used	22

49.4.8.5 Baud rate generation

The value in WF7816[GTFD] does not impact the clock frequency. SBR and BRFD are used to generate the clock frequency. This clock frequency is used by the UART only and is not seen by the smartcard device. The transmitter clocks operates at 1/16 the frequency of the receive clock so that the receiver is able to sample the received value 16 times during the ETU.

49.4.8.6 UART restrictions in ISO-7816 operation

Due to the flexibility of the UART module, there are several features and interrupts that are not supported while running in ISO-7816 mode. These restrictions are documented within the register field definitions.

49.4.9 Infrared interface

The UART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the UART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This design covers data rates only between 2.4 kbits/s and 115.2 kbits/s.

The UART has an infrared transmit encoder and receive decoder. The UART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the MCU. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the UART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active low pulses.

The infrared submodule receives its clock sources from the UART. One of these two clocks are selected in the infrared submodule to generate either 3/16, 1/16, 1/32, or 1/4 narrow pulses during transmission.

49.4.9.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a zero bit and no pulse for a one bit. The narrow pulse is sent in the middle of the bit with a duration of 1/32, 1/16, 3/16, or 1/4 of a bit time. A narrow high pulse is transmitted for a zero bit when C3[TXINV] is cleared, while a narrow low pulse is transmitted for a zero bit when C3[TXINV] is set.

49.4.9.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each zero received and no pulse is expected for each one received. A narrow high pulse is expected for a zero bit when S2[RXINV] is cleared, while a narrow low pulse is expected for a zero bit when S2[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

49.5 Reset

All registers reset to a particular value are indicated in Memory map and registers.

49.6 System level interrupt sources

There are several interrupt signals that are sent from the UART. The following table lists the interrupt sources generated by the UART. The local enables for the UART interrupt sources are described in this table. Details regarding the individual operation of each interrupt are contained under various sub-sections of Memory map and registers. However, RXEDGIF description also outlines additional details regarding the RXEDGIF interrupt because of its complexity of operation. Any of the UART interrupt requests listed in the table can be used to bring the CPU out of Wait mode.

Table 49-357. UART interrupt sources

Interrupt Source	Flag	Local enable	DMA select
Transmitter	TDRE	TIE	TDMAS = 0
Transmitter	TC	TCIE	-
Receiver	IDLE	ILIE	-
Receiver	RDRF	RIE	RDMAS = 0
Receiver	LBKDIF	LBKDIE	-
Receiver	RXEDGIF	RXEDGIE	-
Receiver	OR	ORIE	-
Receiver	NF	NEIE	-
Receiver	FE	FEIE	-
Receiver	PF	PEIE	-
Receiver	RXUF	RXUFE	-
Transmitter	TXOF	TXOFE	-
Receiver	WT	WTWE	-
Receiver	CWT	CWTE	-

Table continues on the next page...

Table 49-357. UART interrupt sources (continued)

Interrupt Source	Flag	Local enable	DMA select
Receiver	BWT	BWTE	-
Receiver	INITD	INITDE	-
Receiver	TXT	TXTE	-
Receiver	RXT	RXTE	-
Receiver	GTV	GTVE	-

49.6.1 RXEDGIF description

S2[RXEDGIF] is set when an active edge is detected on the RxD pin. Therefore, the active edge can be detected only when in two wire mode. A RXEDGIF interrupt is generated only when S2[RXEDGIF] is set. If RXEDGIE is not enabled before S2[RXEDGIF] is set, an interrupt is not generated until S2[RXEDGIF] is set.

49.6.1.1 RxD edge detect sensitivity

Edge sensitivity can be software programmed to be either falling or rising. The polarity of the edge sensitivity is selected using S2[RXINV]. To detect the falling edge, S2[RXINV] is programmed to 0. To detect the rising edge, S2[RXINV] is programmed to 1.

Synchronizing logic is used prior to detect edges. Prior to detecting an edge, the receive data on RxD input must be at the deasserted logic level. A falling edge is detected when the RxD input signal is seen as a logic 1 (the deasserted level) during one module clock cycle, and then a logic 0 (the asserted level) during the next cycle. A rising edge is detected when the input is seen as a logic 0 during one module clock cycle and then a logic 1 during the next cycle.

49.6.1.2 Clearing RXEDGIF interrupt request

Writing a logic 1 to S2[RXEDGIF] immediately clears the RXEDGIF interrupt request even if the RxD input remains asserted. S2[RXEDGIF] remains set if another active edge is detected on RxD while attempting to clear S2[RXEDGIF] by writing a 1 to it.

49.6.1.3 Exit from low-power modes

The receive input active edge detect circuit is still active on low power modes (Wait and Stop). An active edge on the receive input brings the CPU out of low power mode if the interrupt is not masked (S2[RXEDGIF] = 1).

49.7 DMA operation

In the transmitter, S1[TDRE] can be configured to assert a DMA transfer request. In the receiver, S1[RDRF] can be configured to assert a DMA transfer request. The following table shows the configuration field settings required to configure each flag for DMA operation.

Table 49-358. DMA configuration

Flag	Request enable bit	DMA select bit
TDRE	TIE = 1	TDMAS = 1
RDRF	RIE = 1	RDMAS = 1

When a flag is configured for a DMA request, its associated DMA request is asserted when the flag is set. When S1[RDRF] is configured as a DMA request, the clearing mechanism of reading S1, followed by reading D, does not clear the associated flag. The DMA request remains asserted until an indication is received that the DMA transactions are done. When this indication is received, the flag bit and the associated DMA request is cleared. If the DMA operation failed to remove the situation that caused the DMA request, another request is issued.

49.8 Application information

This section describes the UART application information.

49.8.1 Transmit/receive data buffer operation

The UART has independent receive and transmit buffers. The size of these buffers may vary depending on the implementation of the module. The implemented size of the buffers is a fixed constant via PFIFO[TXFIFOSIZE] and PFIFO[RXFIFOSIZE]. Additionally, legacy support is provided that allows for the FIFO structure to operate as a

depth of one. This is the default/reset behavior of the module and can be adjusted using the PFIFO[RXFE] and PFIFO[TXFE] bits. Individual watermark levels are also provided for transmit and receive.

There are multiple ways to ensure that a data block, which is a set of characters, has completed transmission. These methods include:

1. Set TXFIFO[TXWATER] to 0. TDRE asserts when there is no further data in the transmit buffer. Alternatively the S1[TC] flag can be used to indicate when the transmit shift register is also empty.
2. Poll TCFIFO[TXCOUNT]. Assuming that only data for a data block has been put into the data buffer, when TCFIFO[TXCOUNT] = 0, all data has been transmitted or is in the process of transmission.
3. S1[TC] can be monitored. When S1[TC] asserts, it indicates that all data has been transmitted and there is no data currently being transmitted in the shift register.

49.8.2 ISO-7816 initialization sequence

This section outlines how to program the UART for ISO-7816 operation. Elements such as procedures to power up or power down the smartcard, and when to take those actions, are beyond the scope of this description. To set up the UART for ISO-7816 operation:

1. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL. According to the 7816 specification the initial (default) baud rating setting should be Fi = 372 and Di = 1 and a maximum frequency of 5 MHz. In other words, the BDH, BDL, and C4 registers should be programmed such that the transmission frequency provided to the smartcard device must be 1/372th of the clock and must not exceed 5 MHz.
2. Write to set BDH[LBKDIE] = 0.
3. Write to C1 to configure word length, parity, and other configuration fields (LOOPS, RSRC) and set C1[M] = 1, C1[PE] = 1, and C1[PT] = 0.
4. Write to set S2[RWUID] = 0 and S2[LBKDE] = 0.
5. Write to set MODEM[RXRTSE] = 0, MODEM[TXRTSPOL] = 0, MODEM[TXRTSE] = 0, and MODEM[TXCTSE] = 0.

6. Write to set up interrupt enable fields desired (C3[ORIE], C3[NEIE], C3[PEIE], and C3[FEIE])
7. Write to set C4[MAEN1] = 0 and C4[MAEN2] = 0.
8. Write to C5 register and configure DMA control register fields as desired for application.
9. Write to set C7816[INIT] = 1,C7816[TTYPE] = 0, and C7816[ISO_7816E] = 1. Program C7816[ONACK] and C7816[ANACK] as desired.
10. Write to IE7816 to set interrupt enable parameters as desired.
11. Write to ET7816 and set as desired.
12. Write to set C2[ILIE] = 0, C2[RE] = 1, C2[TE] = 1, C2[RWU] = 0, and C2[SBK] = 0. Set up interrupt enables C2[TIE], C2[TCIE], and C2[RIE] as desired.

At this time, the UART will start listening for an initial character. After being identified, it will automatically adjust S2[MSBF], C3[TXINV], and S2[RXINV]. The software must then receive and process an answer to reset. Upon processing the answer to reset, the software must write to set C2[RE] = 0 and C2[TE] = 0. The software should then adjust 7816 specific and UART generic parameters to match and configure data that was received during the answer on reset period. After the new settings have been programmed, including the new baud rate and C7816[TTYPE], C2[RE] and C2[TE] can be reenabled as required.

49.8.2.1 Transmission procedure for (C7816[TTYPE] = 0)

When the protocol selected is C7816[TTYPE] = 0, it is assumed that the software has a prior knowledge of who should be transmitting and receiving. Therefore, no mechanism is provided for automated transmission/receipt control. The software must monitor S1[TDRE], or configure for an interrupt, and provide additional data for transmission, as appropriate. Additionally, software should set C2[TE] = 1 and control TXDIR whenever it is the UART's turn to transmit information. For ease of monitoring, it is suggested that only data be transmitted until the next receiver/transmit switchover is loaded into the transmit FIFO/buffer.

49.8.2.2 Transmission procedure for (C7816[TTYPE] = 1)

When the protocol selected is C7816[TTYPE] = 1, data is transferred in blocks. Before starting a transmission, the software must write the size, in number of bytes, for the Information Field portion of the block into TLEN. If a CRC is being transmitted for the block, the value in TLEN must be one more than the size of the information field. The software must then set C2[TE] = 1 and C2[RE] = 1. The software must then monitor S1[TDRE]/interrupt and write the prologue, information, and epilogue field to the transmit buffer. TLEN automatically decrements, except for prologue bytes and the final epilogue byte. When the final epilogue byte has been transmitted, the UART automatically clears C2[TE] and C3[TXDIR] to 0, and the UART automatically starts capturing the response to the block that was transmitted. After the software has detected the receipt of the response, the transmission process must be repeated as needed with sufficient urgency to ensure that the block wait time and character wait times are not violated.

49.8.3 Initialization sequence (non ISO-7816)

To initiate a UART transmission:

1. Configure the UART.
   a. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL.
   b. Write to C1 to configure word length, parity, and other configuration bits (LOOPS, RSRC, M, WAKE, ILT, PE, and PT). Write to C4, MA1, and MA2 to configure.
   c. Enable the transmitter, interrupts, receiver, and wakeup as required, by writing to C2 (TIE, TCIE, RIE, ILIE, TE, RE, RWU, and SBK), S2 (MSBF and BRK13), and C3 (ORIE, NEIE, PEIE, and FEIE). A preamble or idle character is then shifted out of the transmitter shift register.
2. Transmit procedure for each byte.
   a. Monitor S1[TDRE] by reading S1 or responding to the TDRE interrupt. The amount of free space in the transmit buffer directly using TCFIFO[TXCOUNT] can also be monitored.

b. If the TDRE flag is set, or there is space in the transmit buffer, write the data to be transmitted to (C3[T8]/D). A new transmission will not result until data exists in the transmit buffer.

3. Repeat step 2 for each subsequent transmission.

Note

During normal operation, S1[TDRE] is set when the shift register is loaded with the next data to be transmitted from the transmit buffer and the number of datawords contained in the transmit buffer is less than or equal to the value in TWFIFO[TXWATER]. This occurs 9/16ths of a bit time after the start of the stop bit of the previous frame.

To separate messages with preambles with minimum idle line time, use this sequence between messages.

1. Write the last dataword of the first message to C3[T8]/D.
2. Wait for S1[TDRE] to go high with TWFIFO[TXWATER] = 0, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting C2[TE].
4. Write the first and subsequent datawords of the second message to C3[T8]/D.

49.8.4 Overrun (OR) flag implications

To be flexible, the overrun flag (OR) operates slight differently depending on the mode of operation. There may be implications that need to be carefully considered. This section clarifies the behavior and the resulting implications. Regardless of mode, if a dataword is received while S1[OR] is set, S1[RDRF] and S1[IDLE] are blocked from asserting. If S1[RDRF] or S1[IDLE] were previously asserted, they will remain asserted until cleared.

49.8.4.1 Overrun operation

The assertion of S1[OR] indicates that a significant event has occurred. The assertion indicates that received data has been lost because there was a lack of room to store it in the data buffer. Therefore, while S1[OR] is set, no further data is stored in the data buffer until S1[OR] is cleared. This ensures that the application will be able to handle the overrun condition.

In most applications, because the total amount of lost data is known, the application will attempt to return the system to a known state. Before S1[OR] is cleared, all received data will be dropped. For this, the software does the following.

1. Remove data from the receive data buffer. This could be done by reading data from the data buffer and processing it if the data in the FIFO was still valuable when the overrun event occurred, or using CFIFO[RXFLUSH] to clear the buffer.
2. Clear S1[OR]. Note that if data was cleared using CFIFO[RXFLUSH], then clearing S1[OR] will result in SFIFO[RXUF] asserting. This is because the only way to clear S1[OR] requires reading additional information from the FIFO. Care should be taken to disable the SFIFO[RXUF] interrupt prior to clearing the OR flag and then clearing SFIFO[RXUF] after the OR flag has been cleared.

Note that, in some applications, if an overrun event is responded to fast enough, the lost data can be recovered. For example, when C7816[ISO_7816E] is asserted, C7816[TTYPE]=1 and C7816[ONACK] = 1, the application may reasonably be able to determine whether the lost data will be resent by the device. In this scenario, flushing the receiver data buffer may not be required. Rather, if S1[OR] is cleared, the lost data may be resent and therefore may be recoverable.

When LIN break detect (LBKDE) is asserted, S1[OR] has significantly different behavior than in other modes. S1[OR] will be set, regardless of how much space is actually available in the data buffer, if a LIN break character has been detected and the corresponding flag, S2[LBKDIF], is not cleared before the first data character is received after S2[LBKDIF] asserted. This behavior is intended to allow the software sufficient time to read the LIN break character from the data buffer to ensure that a break character was actually detected. The checking of the break character was used on some older implementations and is therefore supported for legacy reasons. Applications that do not require this checking can simply clear S2[LBKDIF] without checking the stored value to ensure it is a break character.

49.8.5 Overrun NACK considerations

When C7816[ISO_7816E] is enabled and C7816[TTYPE] = 0, the retransmission feature of the 7816 protocol can be used to help avoid lost data when the data buffer overflows. Using C7816[ONACK], the module can be programmed to issue a NACK on an overflow event. Assuming that the smartcard device has implemented retransmission, the lost data will be retransmitted. While useful, there is a programming implication that may require special consideration. The need to transmit a NACK must be determined and committed to prior to the dataword being fully received. While the NACK is being received, it is possible that the application code will read the data buffer such that

sufficient room will be made to store the dataword that is being NACKed. Even if room has been made in the data buffer after the transmission of a NACK is completed, the received data will always be discarded as a result of an overflow and the ET7816[RXTHRESHOLD] value will be incremented by one. However, if sufficient space now exists to write the received data which was NACK'ed, S1[OR] will be blocked and kept from asserting.

49.8.6 Match address registers

The two match address registers allow a second match address function for a broadcast or general call address to the serial bus, as an example.

49.8.7 Modem feature

This section describes the modem features.

49.8.7.1 Ready-to-receive using RTS

To help to stop overrun of the receiver data buffer, the RTS signal can be used by the receiver to indicate to another UART that it is ready to receive data. The other UART can send the data when its CTS signal is asserted. This handshaking conforms to the TIA-232-E standard. A transceiver is necessary if the required voltage levels of the communication link do not match the voltage levels of the UART's RTS and CTS signals.

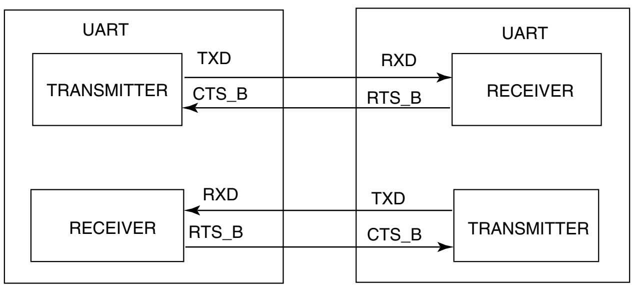

Figure 49-362. Ready-to-receive

The transmitter's CTS signal can be used for hardware flow control whether its RTS signal is used for hardware flow control, transceiver driver enable, or not at all.

49.8.7.2 Transceiver driver enable using RTS

RS-485 is a multiple drop communication protocol in which the UART transceiver's driver is 3-stated unless the UART is driving. The RTS signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS can be matched to the polarity of the transceiver's driver enable signal. See the following figure.

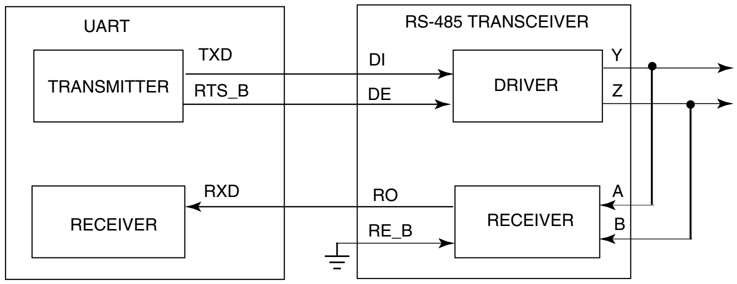

Figure 49-363. Transceiver driver enable using RTS

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the UART in single wire mode, freeing the RXD pin for other uses.

49.8.8 IrDA minimum pulse width

The IrDA specifies a minimum pulse width of 1.6 µs. The UART hardware does not include a mechanism to restrict/force the pulse width to be greater than or equal to 1.6 µs. However, configuring the baud rate to 115.2 kbit/s and the narrow pulse width to 3/16 of a bit time results in a pulse width of 1.6 µs.

49.8.9 Clearing 7816 wait timer (WT, BWT, CWT) interrupts

The 7816 wait timer interrupts associated with IS7816[WT], IS7816[BWT], and IS7816[CWT] will automatically reassert if they are cleared and the wait time is still violated. This behavior is similar to most of the other interrupts on the UART. In most cases, if the condition that caused the interrupt to trigger still exists when the interrupt is cleared, then the interrupt will reassert. For example, consider the following scenario:

1. IS7816[WT] is programmed to assert after 9600 cycles of unresponsiveness.
2. The 9600 cycles pass without a response resulting in the WT interrupt asserting.
3. The IS7816[WT] is cleared at cycle 9700 by the interrupt service routine.

4. After the WT interrupt has been cleared, the smartcard remains unresponsive. At cycle 9701 the WT interrupt will be reasserted.

If the intent of clearing the interrupt is such that it does not reassert, the interrupt service routine must remove or clear the condition that originally caused the interrupt to assert prior to clearing the interrupt. There are multiple ways that this can be accomplished, including ensuring that an event that results in the wait timer resetting occurs, such as, the transmission of another packet.

49.8.10 Legacy and reverse compatibility considerations

Recent versions of the UART have added several new features. Whenever reasonably possible, reverse compatibility was maintained. However, in some cases this was either not feasible or the behavior was deemed as not intended. This section describes several differences to legacy operation that resulted from these recent enhancements. If application code from previous versions is used, it must be reviewed and modified to take the following items into account. Depending on the application code, additional items that are not listed here may also need to be considered.

1. Various reserved registers and register bits are used, such as, MSFB and M10.
2. This module now generates an error when invalid address spaces are used.
3. While documentation indicated otherwise, in some cases it was possible for S1[IDLE] to assert even if S1[OR] was set.
4. S1[OR] will be set only if the data buffer (FIFO) does not have sufficient room. Previously, the data buffer was always a fixed size of one and the S1[OR] flag would set so long as S1[RDRF] was set even if there was room in the data buffer. While the clearing mechanism has remained the same for S1[RDRF], keeping the OR flag assertion tied to the RDRF event rather than the data buffer being full would have greatly reduced the usefulness of the buffer when its size is larger than one.
5. Previously, when C2[RWU] was set (and WAKE = 0), the IDLE flag could reassert up to every bit period causing an interrupt and requiring the host processor to reassert C2[RWU]. This behavior has been modified. Now, when C2[RWU] is set (and WAKE = 0), at least one non-idle bit must be detected before an idle can be detected.

Chapter 50
Secured digital host controller (SDHC)

50.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The chapter is intended for a module driver software developer. It describes module-level operation and programming.

50.2 Overview

50.2.1 Supported types of cards

Different types of cards supported by the SDHC are described briefly as follows:

The multimedia card (MMC) is a universal low-cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming. Old MMC cards are based on a 7-pin serial bus with a single data pin, while the new high-speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

The secure digital card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are forward compatible with the old MMC with some additions.

Under the SD protocol, it can be categorized into memory card, I/O card and combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the figure does not show cards with reduced size or mini cards.

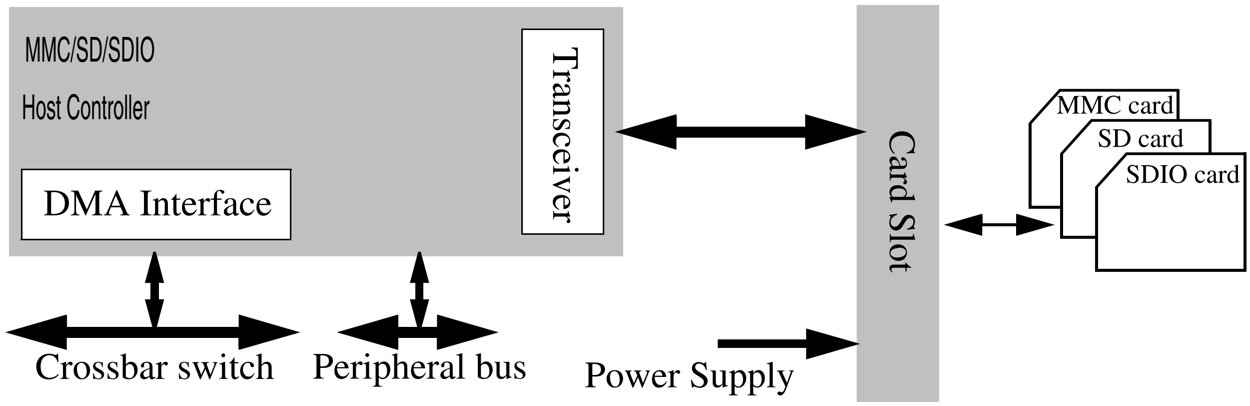

Figure 50-1. System connection of the SDHC

50.2.2 SDHC block diagram

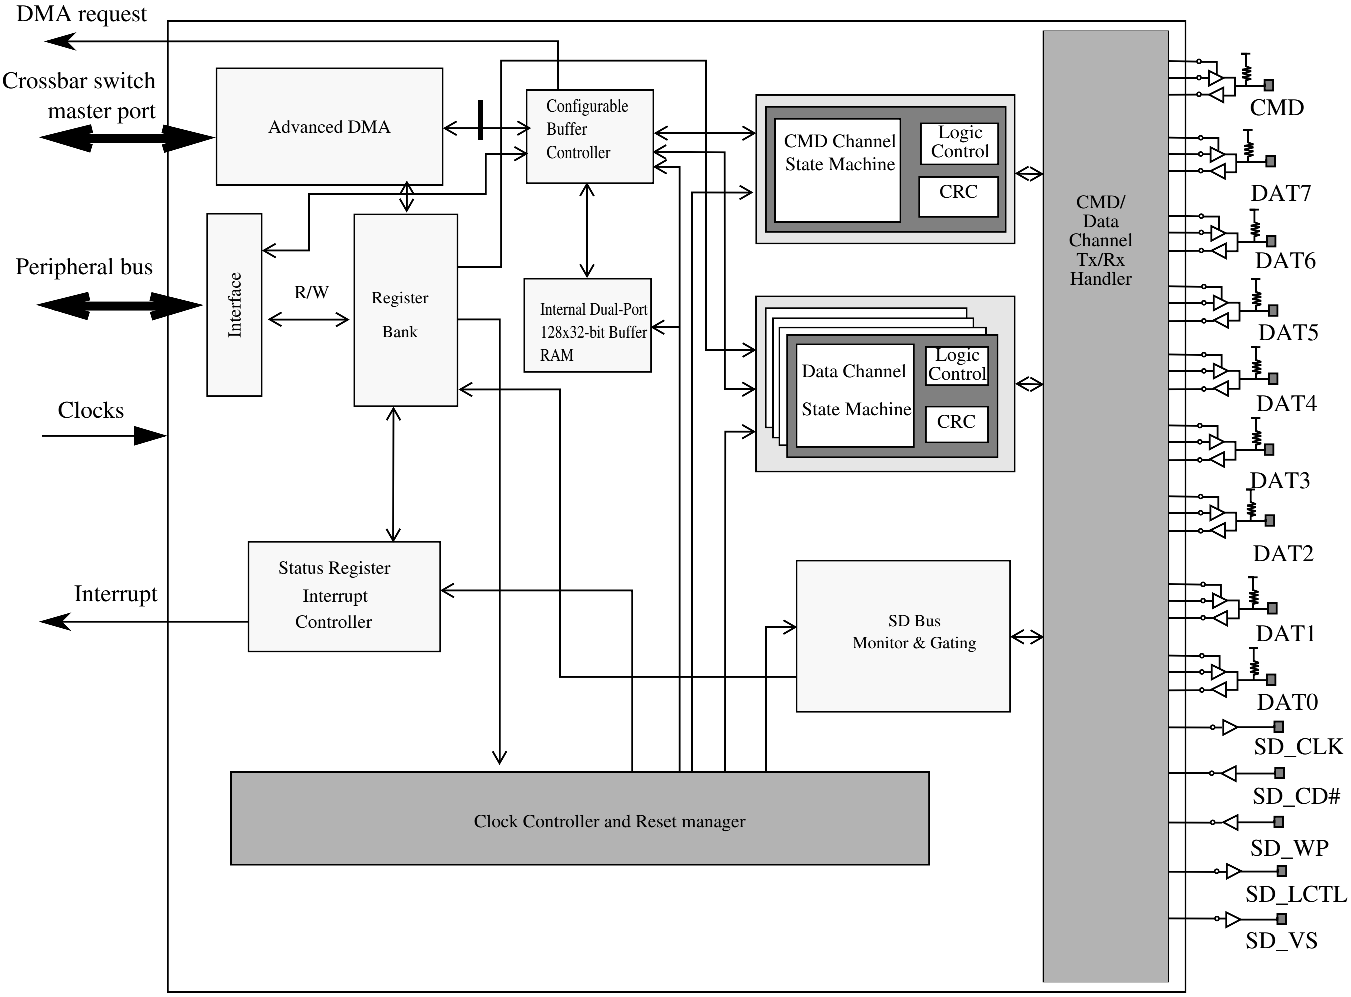

Figure 50-2. Enhanced secure digital host controller block diagram

50.2.3 Features

The features of the SDHC module include:

- Conforms to the SD Host Controller Standard Specification version 2.0 including test event register support
- Compatible with the MMC System Specification version 4.2/4.3
- Compatible with the SD Memory Card Specification version 2.0 and supports the high capacity SD memory card
- Compatible with the SDIO Card Specification version 2.0

- Designed to work with SD memory, miniSD memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 52 MHz
- Supports 1-bit/4-bit SD and SDIO modes, 1-bit/4-bit / 8-bit MMC modesdevices
    - Up to 200 Mbps of data transfer for SD/SDIO cards using 4 parallel data lines
    - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in Single Data Rate (SDR) mode
- Supports single block, multiblock read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort (both hardware and software CMD12)
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports auto CMD12 for multiblock transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Supports advanced DMA to perform linked memory access

50.2.4 Modes and operations

The SDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit

- MMC 8-bit
- Identification mode up to 400 kHz
- MMC Full Speed mode up to 20 MHz
- MMC High Speed mode up to 52 MHz
- SD/SDIO Full Speed mode up to 25 MHz
- SD/SDIO High Speed mode up to 50 MHz

50.3 SDHC signal descriptions

Table 50-1. SDHC signal descriptions

Signal	Description	I/O
SDHC_DCLK	Generated clock used to drive the MMC, SD, SDIO or CE-ATA cards.	O
SDHC_CMD	Send commands to and receive responses from the card.	I/O
SDHC_D0	DAT0 line or busy-state detect	I/O
SDHC_D1	8-bit mode: DAT1 line 4-bit mode: DAT1 line or interrupt detect 1-bit mode: Interrupt detect	I/O
SDHC_D2	4-/8-bit mode: DAT2 line or read wait 1-bit mode: Read wait	I/O
SDHC_D3	4-/8-bit mode: DAT3 line or configured as card detection pin 1-bit mode: May be configured as card detection pin	I/O
SDHC_D4	DAT4 line in 8-bit mode Not used in other modes	I/O
SDHC_D5	DAT5 line in 8-bit mode Not used in other modes	I/O
SDHC_D6	DAT6 line in 8-bit mode Not used in other modes	I/O
SDHC_D7	DAT7 line in 8-bit mode Not used in other modes	I/O

50.4 Memory map and register definition

This section includes the module memory map and detailed descriptions of all registers.

SDHC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400B_1000	DMA System Address register (SDHC0_DSADDR)	32	R/W	0000_0000h	50.4.1/2742

SDHCx_DSADDR field descriptions

Field	Description
31–2 DSADDR	DMA System Address Contains the 32-bit system memory address for a DMA transfer. Because the address must be word (4 bytes) align, the least 2 bits are reserved, always 0. When the SDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing, that is, after a transaction has stopped. Read operation during transfers may return an invalid value. The host driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver shall wait, until PRSSTAT[DLA] is cleared, before writing to this register. The SDHC internal DMA does not support a virtual memory system. It supports only continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, SDHC will automatically change SEQ burst type to NSEQ. Because this register supports dynamic address reflecting, when IRQSTAT[TC] bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when IRQSTAT[TC] is set.
1–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

50.4.2 Block Attributes register (SDHCx_BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BLKCNT																0			BLKSIZE												
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDHCx_BLKATTR field descriptions

Field	Description
31–16 BLKCNT	Blocks Count For Current Transfer This register is enabled when XFERTYP[BCEN] is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The host driver shall set this register to a value between 1 and the maximum block count. The SDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register must be accessed only when no transaction is executing, that is, after transactions are stopped. During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer content as a result of a suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register must be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when suspend command is sent out, SDHC will regard the current transfer as aborted and change BLKCNT back to its original value instead of keeping the dynamical indicator of remained block count. When restoring transfer content prior to issuing a resume command, the host driver shall restore the previously saved block count. **NOTE:** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when XFERTYP[MSBSEL] is 0, indicating a single block transfer, the read value of BLKCNT is always 1. 0000h Stop count. 0001h 1 block 0002h 2 blocks ... FFFFh 65535 blocks
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–0 BLKSIZE	Transfer Block Size Specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing, that is, after a transaction has stopped. Read operations during transfers may return an invalid value, and write operations will be ignored. 000h No data transfer. 001h 1 Byte 002h 2 Bytes 003h 3 Bytes 004h 4 Bytes ... 1FFh 511 Bytes 200h 512 Bytes ... 800h 2048 Bytes ... 1000h 4096 Bytes

50.4.3 Command Argument register (SDHCx_CMDARG)

This register contains the SD/MMC command argument.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CMDARG																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDHCx_CMDARG field descriptions

Field	Description
31–0 CMDARG	Command Argument The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This register is write protected when PRSSTAT[CDIHB0] is set.

50.4.4 Transfer Type register (SDHCx_XFERTYP)

This register is used to control the operation of data transfers. The host driver shall set this register before issuing a command followed by a data transfer, or before issuing a resume command. To prevent data loss, the SDHC prevents writing to the bits that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver shall check PRSSTAT[CDIHB] and PRSSTAT[CIHB] before writing to this register. When PRSSTAT[CDIHB] is set, any attempt to send a command with data by writing to this register is ignored; when PRSSTAT[CIHB] bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is nonzero. Besides, block count must also be nonzero, or indicated as single block transfer (bit 5 of this register is 0 when written), or block count is disabled (bit 1 of this register is 0 when written), otherwise SDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is 1), otherwise SDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, that is, response time-out, SDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver must issue the command again to retry the transfer. It is also possible that, for some reason, the card responds to the

command but SDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The following table shows the summary of how register settings determine the type of data transfer.

Table 50-40. Transfer Type register setting for various transfer types

Multi/Single block select	Block count enable	Block count	Function
0	Don't care	Don't care	Single transfer
1	0	Don't care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

The following table shows the relationship between XFERTYP[CICEN] and XFERTYP[CCCEN], in regards to XFERTYP[RSPTYP] as well as the name of the response type.

Table 50-41. Relationship between parameters and the name of the response type

Response type (RSPTYP)	Index check enable (CICEN)	CRC check enable (CCCEN)	Name of response type
00	0	0	No Response
01	0	1	IR2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

NOTE

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the SDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

SDHCx_XFERTYP field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–24 CMDINX	Command Index These bits shall be set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP	Command Type There are three types of special commands: suspend, resume, and abort. These bits shall be set to 00b for all other commands. • Suspend command: If the suspend command succeeds, the SDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DAT line. Because the SDHC does not monitor the content of command response, it does not know if the suspend command succeeded or not. It is the host driver's responsibility to check the status of the suspend command and send another command marked as suspend to inform the SDHC that a suspend command was successfully issued. After the end bit of command is sent, the SDHC deasserts read wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the suspend command fails, the SDHC will maintain its current state, and the host driver shall restart the transfer by setting PROCTL[CREQ]. • Resume command: The host driver restarts the data transfer by restoring the registers saved before sending the suspend command and then sends the resume command. The SDHC will check for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, the SDHC will stop reads to the buffer. If this command is set when executing a write transfer, the SDHC will stop driving the DAT line. After issuing the abort command, the host driver must issue a software reset (abort transaction). 00b Normal other commands. 01b Suspend CMD52 for writing bus suspend in CCCR. 10b Resume CMD52 for writing function select in CCCR. 11b Abort CMD12, CMD52 for writing I/O abort in CCCR.
21 DPSEL	Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following:

Table continues on the next page...

SDHCx_XFERTYP field descriptions (continued)

Field	Description
	• Commands using only the CMD line, for example: CMD52. • Commands with no data transfer, but using the busy signal on DAT[0] line, R1b or R5b, for example: CMD38. **NOTE:** In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, that is, the WPSPL bit is active as 0, any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored. 0b No data present. 1b Data present.
20 CICEN	Command Index Check Enable If this bit is set to 1, the SDHC will check the index field in the response to see if it has the same value as the command index. If it is not, it is reported as a command index error. If this bit is set to 0, the index field is not checked. 0b Disable 1b Enable
19 CCCEN	Command CRC Check Enable If this bit is set to 1, the SDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. 0b Disable 1b Enable
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 RSPTYP	Response Type Select 00b No response. 01b Response length 136. 10b Response length 48. 11b Response length 48, check busy after response.
15–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 MSBSEL	Multi/Single Block Select Enables multiple block DAT line data transfers. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the block count register. 0b Single block. 1b Multiple blocks.
4 DTDSEL	Data Transfer Direction Select Defines the direction of DAT line data transfers. The bit is set to 1 by the host driver to transfer data from the SD card to the SDHC and is set to 0 for all other commands. 0b Write host to card. 1b Read card to host.

Table continues on the next page...

SDHCx_XFERTYP field descriptions (continued)

Field	Description
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 AC12EN	Auto CMD12 Enable Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the SDHC will issue a CMD12 automatically when the last block transfer has completed. The host driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the SDHC will ignore this bit whether it is set or not. 0b Disable 1b Enable
1 BCEN	Block Count Enable Used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b Disable 1b Enable
0 DMAEN	DMA Enable Enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the host driver sets the DPSEL bit of this register. Whether the simple DMA, or the advanced DMA, is active depends on PROCTL[DMAS]. 0b Disable 1b Enable

50.4.5 Command Response 0 (SDHCx_CMDRSP0)

This register is used to store part 0 of the response bits from the card.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDHCx_CMDRSP1 field descriptions

Field	Description
31–0 CMDRSP1	Command Response 1

50.4.7 Command Response 2 (SDHCx_CMDRSP2)

This register is used to store part 2 of the response bits from the card.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CMDRSP2																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDHCx_CMDRSP2 field descriptions

Field	Description
31–0 CMDRSP2	Command Response 2

50.4.8 Command Response 3 (SDHCx_CMDRSP3)

This register is used to store part 3 of the response bits from the card.

The following table describes the mapping of command responses from the SD bus to command response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 50-46. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (Auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bit of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bit of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the SDHC stores only a part of the response data in the command response registers. This enables the host driver to efficiently read 32-bit of response data in one read cycle on a 32-bit bus system. Parts of the response, the index field and the CRC, are checked by the SDHC, as specified by XFERTYP[CICEN] and XFERTYP[CCCEN], and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the SDHC will check R[47:1], and if the response length is 136 the SDHC will check R[119:1].

Because the SDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the SDHC stores the auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows the SDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the SDHC modifies part of the command response registers, as shown in the table above, it preserves the unmodified bits.

Address: Base address + 1Ch offset

SDHCx_DATPORT field descriptions

Field	Description
31–0 DATCONT	Data Content The Buffer Data Port register is for 32-bit data access by the CPU or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

50.4.10 Present State register (SDHCx_PRSSTAT)

The host driver can get status of the SDHC from this 32-bit read-only register.

NOTE

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DAT lines are busy during a data transfer. These commands can be issued when Command Inhibit (CIHB) is set to zero. Other commands shall be issued when Command Inhibit (CDIHB) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

SDHCx_PRSSTAT field descriptions

Field	Description
31–24 DLSL	DAT Line Signal Level Used to check the DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The reset value is effected by the external pullup/pulldown resistors. By default, the read value of this field after reset is 8'b11110111, when DAT[3] is pulled down and the other lines are pulled up. DAT[0] Data 0 line signal level. DAT[1] Data 1 line signal level. DAT[2] Data 2 line signal level. DAT[3] Data 3 line signal level. DAT[4] Data 4 line signal level. DAT[5] Data 5 line signal level. DAT[6] Data 6 line signal level. DAT[7] Data 7 line signal level.

Table continues on the next page...

SDHCx_PRSSTAT field descriptions (continued)

Field	Description
23 CLSL	CMD Line Signal Level Used to check the CMD line level to recover from errors, and for debugging. The reset value is effected by the external pullup/pulldown resistor, by default, the read value of this bit after reset is 1b, when the command line is pulled up.
22–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 WPSPL	Write Protect Switch Pin Level The write protect switch is supported for memory and combo cards.This bit reflects the inverted value of the SD_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SD_WP pin is not used, it must be tied low, so that the reset value of this bit is high and write is enabled. 0b Write protected (SD_WP=1). 1b Write enabled (SD_WP=0).
18 CDPL	Card Detect Pin Level This bit reflects the inverse value of the SD_CD# pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the SD_CD# pin (that is, when a card is inserted in the socket, it is 0 on the SD_CD# input, and consequently the CDPL reads 1.) 0b No card present (SD_CD#=1). 1b Card present (SD_CD#=0).
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CINS	Card Inserted Indicates whether a card has been inserted. The SDHC debounces this signal so that the host driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a card insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a card removal interrupt in the Interrupt Status register. A write to the force event register does not effect this bit. SYSCTL[RSTA] does not effect this bit. A software reset does not effect this bit. 0b Power on reset or no card. 1b Card inserted.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 BREN	Buffer Read Enable Used for non-DMA read transfers. The SDHC may implement multiple buffers to transfer data efficiently. This read-only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. This read-only flag indicates that valid data exists in the host side buffer. 0b Read disable, valid data less than the watermark level exist in the buffer. 1b Read enable, valid data greater than the watermark level exist in the buffer.
10 BWEN	Buffer Write Enable

Table continues on the next page...

SDHCx_PRSSTAT field descriptions (continued)

Field	Description
	Used for non-DMA write transfers. The SDHC can implement multiple buffers to transfer data efficiently. This read-only flag indicates whether space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. This read-only flag indicates whether space is available for write data. 0b Write disable, the buffer can hold valid data less than the write watermark level. 1b Write enable, the buffer can hold valid data greater than the write watermark level.
9 RTA	Read Transfer Active Used for detecting completion of a read transfer. This bit is set for either of the following conditions: • After the end bit of the read command. • When writing a 1 to PROCTL[CREQ] to restart a read transfer. A transfer complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the system, that is, all data are read away from SDHC internal buffer. • When all valid data blocks have been transferred from SDHC internal buffer to the system and no current block transfers are being sent as a result of the stop at block gap request being set to 1. 0b No valid data. 1b Transferring data.
8 WTA	Write Transfer Active Indicates that a write transfer is active. If this bit is 0, it means no valid write data exists in the SDHC. This bit is set in either of the following cases: • After the end bit of the write command. • When writing 1 to PROCTL[CREQ] to restart a write transfer. This bit is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (single and multiple). • After getting the CRC status of any block where data transmission is about to be stopped by a stop at block gap request. During a write transaction, a block gap event interrupt is generated when this bit is changed to 0, as result of the stop at block gap request being set. This status is useful for the host driver in determining when to issue commands during write busy state. 0b No valid data. 1b Transferring data.
7 SDOFF	SD Clock Gated Off Internally Indicates that the SD clock is internally gated off, because of buffer over/under-run or read pause without read wait assertion, or the driver has cleared SYSCTL[SDCLKEN] to stop the SD clock. This bit is for the host driver to debug data transaction on the SD bus. 0b SD clock is active. 1b SD clock is gated off.
6 PEROFF	SDHC clock Gated Off Internally Indicates that the is internally gated off. This bit is for the host driver to debug transaction on the SD bus. When INITA bit is set, SDHC sending 80 clock cycles to the card, SDCLKEN must be 1 to enable the

Table continues on the next page...

SDHCx_PRSSTAT field descriptions (continued)

Field	Description
	output card clock, otherwise the will never be gate off, so and will be always active. SDHC clockSDHC clockSDHC clockbus clock 0b SDHC clock is active. 1b SDHC clock is gated off.
5 HCKOFF	System Clock Gated Off Internally Indicates that the system clock is internally gated off. This bit is for the host driver to debug during a data transfer. 0b System clock is active. 1b System clock is gated off.
4 IPGOFF	Bus Clock Gated Off Internally Indicates that the bus clock is internally gated off. This bit is for the host driver to debug. 0b Bus clock is active. 1b Bus clock is gated off.
3 SDSTB	SD Clock Stable Indicates that the internal card clock is stable. This bit is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear SYSCTL[SDCLKEN] to remove glitch on the card clock when the frequency is changing. 0b Clock is changing frequency and not stable. 1b Clock is stable.
2 DLA	Data Line Active Indicates whether one of the DAT lines on the SD bus is in use. **In the case of read transactions:** This status indicates whether a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a block gap event interrupt in the Interrupt Status register. This bit will be set in either of the following cases: • After the end bit of the read command. • When writing a 1 to PROCTL[CREQ] to restart a read transfer. This bit will be cleared in either of the following cases: 1. When the end bit of the last data block is sent from the SD bus to the SDHC. 2. When the read wait state is stopped by a suspend command and the DAT2 line is released. The SDHC will wait at the next block gap by driving read wait at the start of the interrupt cycle. If the read wait signal is already driven (data buffer cannot receive data), the SDHC can wait for a current block gap by continuing to drive the read wait signal. It is necessary to support read wait to use the suspend / resume function. This bit will remain 1 during read wait.

Table continues on the next page...

SDHCx_PRSSTAT field descriptions (continued)

Field	Description
	In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a transfer complete interrupt in the interrupt status register. This bit will be set in either of the following cases: • After the end bit of the write command. • When writing to 1 to PROCTL[CREQ] to continue a write transfer. This bit will be cleared in either of the following cases: • When the SD card releases write busy of the last data block, the SDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the SDHC shall assume the card drive "Not busy". • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a stop at block gap request. **In the case of command with busy pending:** This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DAT0 line is released. 0b DAT line inactive. 1b DAT line active.
1 CDIHB	Command Inhibit (DAT) This status bit is generated if either the DLA or the RTA is set to 1. If this bit is 0, it indicates that the SDHC can issue the next SD/MMC Command. Commands with a busy signal belong to CDIHB, for example, R1b, R5b type. Except in the case when the command busy is finished, changing from 1 to 0 generates a transfer complete interrupt in the Interrupt Status register. **NOTE:** The SD host driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 0b Can issue command which uses the DAT line. 1b Cannot issue command which uses the DAT line.
0 CIHB	Command Inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and the SDHC can issue a SD/MMC Command using the CMD line. This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the CDIHB bit is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a command complete interrupt in the interrupt status register. If the SDHC cannot issue the command because of a command conflict error (see command CRC error) or because of a command not issued by auto CMD12 error, this bit will remain 1 and the command complete is not set. The status of issuing an auto CMD12 does not show on this bit. 0b Can issue command using only CMD line. 1b Cannot issue command.

50.4.11 Protocol Control register (SDHCx_PROCTL)

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the SDHC issues a suspend command or the SD card accepts the suspend command:

- If the host driver does not issue a suspend command, the continue request shall be used to restart the transfer.
- If the host driver issues a suspend command and the SD card accepts it, a resume command shall be used to restart the transfer.
- If the host driver issues a suspend command and the SD card does not accept it, the continue request shall be used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver shall wait for a transfer complete (in the interrupt status register), before attempting to restart the transfer. When restarting the data transfer by continue request, the host driver shall clear the stop at block gap request before or simultaneously.

SDHCx_PROCTL field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 WECRM	Wakeup Event Enable On SD Card Removal Enables a wakeup event, via IRQSTAT[CRM]. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, IRQSTAT[CRM] and the SDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active to assert IRQSTAT[CRM] and the SDHC interrupt.

Table continues on the next page...

SDHCx_PROCTL field descriptions (continued)

Field	Description
	0b Disabled 1b Enabled
25 WECINS	Wakeup Event Enable On SD Card Insertion Enables a wakeup event, via IRQSTAT[CINS]. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, IRQSTATEN[CINSEN] and the SDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active to assert IRQSTATEN[CINSEN] and the SDHC interrupt. 0b Disabled 1b Enabled
24 WECINT	Wakeup Event Enable On Card Interrupt Enables a wakeup event, via IRQSTAT[CINT]. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the card interrupt status and the SDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active to assert the card interrupt status and the SDHC interrupt. 0b Disabled 1b Enabled
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 IABG	Interrupt At Block Gap Valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card can't signal an interrupt during a multiple block transfer, this bit must be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. 0b Disabled 1b Enabled
18 RWCTL	Read Wait Control The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the SDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the SDHC will stop the SD Clock to pause reading operation. 0b Disable read wait control, and stop SD clock at block gap when SABGREQ is set. 1b Enable read wait control, and assert read wait without stopping SD clock at block gap when SABGREQ bit is set.
17 CREQ	Continue Request Used to restart a transaction which was stopped using the PROCTL[SABGREQ]. When a suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set PROCTL[SABGREQ] to 0 and set this bit to 1 to restart the transfer. The SDHC automatically clears this bit, therefore it is not necessary for the host driver to set this bit to 0. If both PROCTL[SABGREQ] and this bit are 1, the continue request is ignored.

Table continues on the next page...

SDHCx_PROCTL field descriptions (continued)

Field	Description
	0b No effect. 1b Restart
16 SABGREQ	Stop At Block Gap Request Used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the IRQSTATEN[TCSEN] is set to 1, indicating a transfer completion, the host driver shall leave this bit set to 1. Clearing both PROCTL[SABGREQ] and PROCTL[CREQ] does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The SDHC will honor the PROCTL[SABGREQ] for write transfers, but for read transfers it requires that SDIO card support read wait. Therefore, the host driver shall not set this bit during read transfers unless the SDIO card supports read wait and has set PROCTL[RWCTL] to 1, otherwise the SDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the data port register, the host driver shall set this bit after all block data is written. If this bit is set to 1, the host driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the host driver shall not clear this bit before IRQSTATEN[TCSEN] is set, otherwise the SDHC's behavior is undefined. This bit effects PRSSTAT[RTA], PRSSTAT[WTA], and PRSSTAT[CDIHB]. 0b Transfer 1b Stop
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 DMAS	DMA Select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 No DMA or simple DMA is selected. 01 ADMA1 is selected. 10 ADMA2 is selected. 11 Reserved
7 CDSS	Card Detect Signal Selection Selects the source for the card detection. 0b Card detection level is selected for normal purpose. 1b Card detection test level is selected for test purpose.
6 CDTL	Card Detect Test Level Enabled while the CDSS is set to 1 and it indicates card insertion. 0b Card detect test level is 0, no card inserted. 1b Card detect test level is 1, card inserted.
5–4 EMODE	Endian Mode The SDHC supports all four endian modes in data transfer. 00b Big endian mode 01b Half word big endian mode 10b Little endian mode 11b Reserved

Table continues on the next page...

SDHCx_PROCTL field descriptions (continued)

Field	Description
3 D3CD	DAT3 As Card Detection Pin If this bit is set, DAT3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DAT3 is also a chip-select for the SPI mode. A pulldown on this pin and CMD0 may set the card into the SPI mode, which the SDHC does not support. Note: Keep this bit set if SDIO interrupt is used. 0b DAT3 does not monitor card Insertion. 1b DAT3 as card detection pin.
2–1 DTW	Data Transfer Width Selects the data width of the SD bus for a data transfer. The host driver shall set it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00b 1-bit mode 01b 4-bit mode 10b 8-bit mode 11b Reserved
0 LCTL	LED Control This bit, fully controlled by the host driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands. 0b LED off. 1b LED on.

50.4.12 System Control register (SDHCx_SYSCTL)

SDHCx_SYSCTL field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 INITA	Initialization Active When this bit is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this bit is self-cleared. This bit is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the PRSSTAT[CIHB] and PRSSTAT[CDIHB] bits are set, writing 1 to this bit is ignored, that is, when command line or data lines are active, write to this bit is not allowed. On the otherhand, when this bit is set, that is, during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self-cleared.
26 RSTD	Software Reset For DAT Line Only part of the data circuit is reset. DMA circuit is also reset. The following registers and bits are cleared by this bit: • Data Port register • Buffer Is Cleared And Initialized.Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active

Table continues on the next page...

SDHCx_SYSCTL field descriptions (continued)

Field	Description
	• Write Transfer Active • DAT Line Active • Command Inhibit (DAT) Protocol Control register • Continue Request • Stop At Block Gap Request Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete 0b No reset. 1b Reset.
25 RSTC	Software Reset For CMD Line Only part of the command circuit is reset. The following registers and bits are cleared by this bit: • PRSSTAT[CIHB] • IRQSTAT[CC] 0b No reset. 1b Reset.
24 RSTA	Software Reset For ALL Effects the entire host controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the host driver shall set this bit to 1 to reset the SDHC. The SDHC shall reset this bit to 0 when the capabilities registers are valid and the host driver can read them. Additional use of software reset for all does not affect the value of the capabilities registers. After this bit is set, it is recommended that the host driver reset the external card and reinitialize it. 0b No reset. 1b Reset.
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 DTOCV	Data Timeout Counter Value Determines the interval by which DAT line timeouts are detected. See IRQSTAT[DTOE] for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value. The host driver can clear IRQSTATEN[DTOESEN] to prevent inadvertent time-out events. 0000b SDCLK x 2^{13} 0001b SDCLK x 2^{14} ... 1110b SDCLK x 2^{27} 1111b Reserved
15–8 SDCLKFS	SDCLK Frequency Select Used to select the frequency of the SDCLK pin. The frequency is not programmed directly. Rather this register holds the prescaler (this register) and divisor (next register) of the base clock frequency register. Setting 00h bypasses the frequency prescaler of the SD Clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of SDHC clock and the following divisor bits.

Table continues on the next page...

SDHCx_SYSCTL field descriptions (continued)

Field	Description
	The frequency of SDCLK is set by the following formula: Clock frequency = (Base clock) / (prescaler x divisor) For example, if the base clock frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input base clock (SDHC clock) is about 96 MHz, the default SD clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD clock frequency is 50 MHz and shall never exceed this limit. Only the following settings are allowed: 01h Base clock divided by 2. 02h Base clock divided by 4. 04h Base clock divided by 8. 08h Base clock divided by 16. 10h Base clock divided by 32. 20h Base clock divided by 64. 40h Base clock divided by 128. 80h Base clock divided by 256.
7–4 DVS	Divisor Used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisor without deterioration of duty cycle. The setting are as following: 0h Divisor by 1. 1h Divisor by 2. ... Eh Divisor by 15. Fh Divisor by 16.
3 SDCLKEN	SD Clock Enable The host controller shall stop SDCLK when writing this bit to 0. SDCLK frequency can be changed when this bit is 0. Then, the host controller shall maintain the same clock frequency until SDCLK is stopped (stop at SDCLK = 0). If the IRQSTAT[CINS] is cleared, this bit must be cleared by the host driver to save power.
2 PEREN	Peripheral Clock Enable If this bit is set, SDHC clock will always be active and no automatic gating is applied. Thus the SDCLK is active except for when auto gating-off during buffer danger (buffer about to over-run or under-run). When this bit is cleared, the SDHC clock will be automatically off whenever there is no transaction on the SD bus. Because this bit is only a feature enabling bit, clearing this bit does not stop SDCLK immediately. The SDHC clock will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • A soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or

Table continues on the next page...

SDHCx_SYSCTL field descriptions (continued)

Field	Description
	• Card external interrupt is detected, or • 80 clocks for initialization phase is ongoing 0b SDHC clock will be internally gated off. 1b SDHC clock will not be automatically gated off.
1 HCKEN	System Clock Enable If this bit is set, system clock will always be active and no automatic gating is applied. When this bit is cleared, system clock will be automatically off when no data transfer is on the SD bus. 0b System clock will be internally gated off. 1b System clock will not be automatically gated off.
0 IPGEN	IPG Clock Enable If this bit is set, bus clock will always be active and no automatic gating is applied. The bus clock will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • Soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • The SDHC clock is not gated off **NOTE:** The bus clock will not be auto gated off if the SDHC clock is not gated off. So clearing only this bit has no effect unless the PEREN bit is also cleared. 0b Bus clock will be internally gated off. 1b Bus clock will not be automatically gated off.

50.4.13 Interrupt Status register (SDHCx_IRQSTAT)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the CTOE and the CC bits.

Table 50-52. SDHC status for CTOE/CC bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

Table 50-53. SDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC Error (CCE) and Command Timeout Error (CTOE).

Table 50-54. SDHC status for CCE/CTOE Bit Combinations

Command complete	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

SDHCx_IRQSTAT field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 DMAE	DMA Error Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver shall restart the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DSADDR value or from the remaining number of blocks and the block size. 0b No error. 1b Error.
27–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 AC12E	Auto CMD12 Error Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error. 0b No error. 1b Error.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBE	Data End Bit Error Occurs either when detecting 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC. 0b No error. 1b Error.
21 DCE	Data CRC Error Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the Write CRC status having a value other than 010. 0b No error. 1b Error.

Table continues on the next page...

SDHCx_IRQSTAT field descriptions (continued)

Field	Description
20 DTOE	Data Timeout Error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b,R5b type • Busy time-out after Write CRC status • Read Data time-out 0b No error. 1b Time out.
19 CIE	Command Index Error Occurs if a Command Index error occurs in the command response. 0b No error. 1b Error.
18 CEBE	Command End Bit Error Occurs when detecting that the end bit of a command response is 0. 0b No error. 1b End Bit Error generated.
17 CCE	Command CRC Error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0, indicating no time-out, this bit is set when detecting a CRC error in the command response. • The SDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the SDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the SDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict. 0b No error. 1b CRC Error generated.
16 CTOE	Command Timeout Error Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the SDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set, this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the SDHC. 0b No error. 1b Time out.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 CINT	Card Interrupt This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the SDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this bit to 1 can clear this bit, but as the interrupt factor from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt factor from the external card followed by a writing 1 to this bit.

Table continues on the next page...

SDHCx_IRQSTAT field descriptions (continued)

Field	Description
	When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (it must reset the interrupt factors in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0b No Card Interrupt. 1b Generate Card Interrupt.
7 CRM	Card Removal This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the host driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register must be confirmed. Because the card state may possibly be changed when the host driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. To leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register. 0b Card state unstable or inserted. 1b Card removed.
6 CINS	Card Insertion This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the host driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register must be confirmed. Because the card state may possibly be changed when the host driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. To leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register. 0b Card state unstable or removed. 1b Card inserted.
5 BRR	Buffer Read Ready This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. See the Buffer Read Enable bit in the Present State register for additional information. 0b Not ready to read buffer. 1b Ready to read buffer.
4 BWR	Buffer Write Ready This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. See the Buffer Write Enable bit in the Present State register for additional information. 0b Not ready to write buffer. 1b Ready to write buffer.
3 DINT	DMA Interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set. 0b No DMA Interrupt. 1b DMA Interrupt is generated.

Table continues on the next page...

SDHCx_IRQSTAT field descriptions (continued)

Field	Description
2 BGE	Block Gap Event If PROCTL[SABGREQ] is set, this bit is set when a read or write transaction is stopped at a block gap. If PROCTL[SABGREQ] is not set to 1, this bit is not set to 1. In the case of a read transaction: This bit is set at the falling edge of the DAT line active status, when the transaction is stopped at SD Bus timing. The read wait must be supported in order to use this function. In the case of write transaction: This bit is set at the falling edge of write transfer active status, after getting CRC status at SD bus timing. 0b No block gap event. 1b Transaction stopped at block gap.
1 TC	Transfer Complete This bit is set when a read or write transfer is completed. In the case of a read transaction: This bit is set at the falling edge of the read transfer active status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length, after the last data has been read to the host system. The second is when data has stopped at the block gap and completed the data transfer by setting PROCTL[SABGREQ], after valid data has been read to the host system. In the case of a write transaction: This bit is set at the falling edge of the DAT line active status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting PROCTL[SABGREQ], and the data transfers are completed,after valid data is written to the SD card and the busy signal released. 0b Transfer not complete. 1b Transfer complete.
0 CC	Command Complete This bit is set when you receive the end bit of the command response, except Auto CMD12. See PRSSTAT[CIHB]. 0b Command not complete. 1b Command complete.

50.4.14 Interrupt Status Enable register (SDHCx_IRQSTATEN)

Setting the bits in this register to 1 enables the corresponding interrupt status to be set by the specified event. If any bit is cleared, the corresponding interrupt status bit is also cleared, that is, when the bit in this register is cleared, the corresponding bit in interrupt status register is always 0.

NOTE

- Depending on PROCTL[IABG] bit setting, SDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the card interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both IRQSTATEN[CTOESEN] and IRQSTATEN[CCESEN] to 1.

50.4.15 Interrupt Signal Enable register (SDHCx_IRQSIGEN)

This register is used to select which interrupt status is indicated to the host system as the interrupt. All of these status bits share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

50.4.16 Auto CMD12 Error Status Register (SDHCx_AC12ERR)

When the AC12ESEN bit in the Status register is set, the host driver shall check this register to identify what kind of error the Auto CMD12 indicated. This register is valid only when the Auto CMD12 Error status bit is set.

The following table shows the relationship between the Auto CMGD12 CRC error and the Auto CMD12 command timeout error.

Table 50-58. Relationship between Command CRC Error and Command Timeout Error For Auto CMD12

Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the SDHC is going to issue an Auto CMD12:
    - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command.
    - Set bit 0 to 0 if the auto CMD12 is issued.
2. At the end bit of an auto CMD12 response:
    - Check errors corresponding to bits 1-4.
    - Set bits 1-4 corresponding to detected errors.
    - Clear bits 1-4 corresponding to detected errors.
3. Before reading the Auto CMD12 error status bit 7:
    - Set bit 7 to 1 if there is a command that can't be issued.
    - Clear bit 7 if there is no command to issue.

The timing for generating the auto CMD12 error and writing to the command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the command register. So it is suggested to read this register only when IRQSTAT[AC12E] is set. An Auto CMD12 error interrupt is generated when one of the error bits (0-4) is set to 1. The command not issued by auto CMD12 error does not generate an interrupt.

Address: Base address + 3Ch offset

SDHCx_AC12ERR field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an auto CMD12 error (D04-D01) in this register. 0b No error. 1b Not issued.
6–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 AC12IE	Auto CMD12 Index Error Occurs if the command index error occurs in response to a command. 0b No error. 1b Error, the CMD index in response is not CMD12.

Table continues on the next page...

SDHCx_AC12ERR field descriptions (continued)

Field	Description
3 AC12CE	Auto CMD12 CRC Error Occurs when detecting a CRC error in the command response. 0b No CRC error. 1b CRC error met in Auto CMD12 response.
2 AC12EBE	Auto CMD12 End Bit Error Occurs when detecting that the end bit of command response is 0 which must be 1. 0b No error. 1b End bit error generated.
1 AC12TOE	Auto CMD12 Timeout Error Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to 1, the other error status bits (2-4) have no meaning. 0b No error. 1b Time out.
0 AC12NE	Auto CMD12 Not Executed If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an auto CMD12. Setting this bit to 1 means the SDHC cannot issue the auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning. 0b Executed. 1b Not executed.

50.4.17 Host Controller Capabilities (SDHCx_HTCAPBLT)

This register provides the host driver with information specific to the SDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset. Any write to this register is ignored.

Address: Base address + 40h offset

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WRBRSTLEN	Write Burst Length [1]

Table continues on the next page...

SDHCx_WML field descriptions (continued)

Field	Description
	The number of words the SDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
23–16 WRWML	Write Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 RDBRSTLEN	Read Burst Length [2] The number of words the SDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
7–0 RDWML	Read Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

1. Due to system restriction, the actual burst length may not exceed 16.
2. Due to system restriction, the actual burst length may not exceed 16.

50.4.19 Force Event register (SDHCx_FEVT)

The Force Event (FEVT) register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding bit of the Interrupt Status Enable register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status register. A read from this register always results in 0's. To change the corresponding status bits in the interrupt status register, make sure to set SYSCTL[IPGEN] so that bus clock is always active.

Forcing a card interrupt will generate a short pulse on the DAT[1] line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is selfcleared.

Address: Base address + 50h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0 AC12NE	Force Event Auto Command 12 Not Executed Forces AC12ERR[AC12NE] to be set.

50.4.20 ADMA Error Status register (SDHCx_ADMAES)

When an ADMA error interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver must use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data may exist in the host controller.

The host controller generates the ADMA error interrupt when it detects invalid descriptor data (valid = 0) in the ST_FDS state. The host driver can distinguish this error by reading the valid bit of the error descriptor.

Table 50-63. ADMA Error State coding

D01-D00	ADMA Error State when error has occurred	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (change address)	No ADMA error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable descriptor command

Address: Base address + 54h offset

SDHCx_ADSADDR field descriptions

Field	Description
31–2 ADSADDR	ADMA System Address Holds the word address of the executing command in the descriptor table. At the start of ADMA, the host driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a descriptor command. When the ADMA is stopped at the block gap, this register indicates the address of the next executable descriptor command. When the ADMA error interrupt is generated, this register shall hold the valid descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to ‘0’ so the ADMA address is always word-aligned. Because this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set.
1–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

50.4.22 Vendor Specific register (SDHCx_VENDOR)

This register contains the vendor-specific control/status register.

7–0 SVN	Specification Version Number These status bits indicate the host controller specification version. 01h SD host specification version 2.0, supports test event register and ADMA. All others Reserved

50.5 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA crossbar switch interface, dual-port memory wrapper, data/command controller, clock & reset manager, and clock generator.

50.5.1 Data buffer

The SDHC uses one configurable data buffer, so that data can be transferred between the system bus and the SD card, with an optimized manner to maximize throughput between the two clock domains (that is, the IP peripheral clock, and the master clock). The following diagram illustrates the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable, and can be any number from 1 to 128 words. The burst lengths for read and write are also configurable, and can be any number from 1 to 31 words.

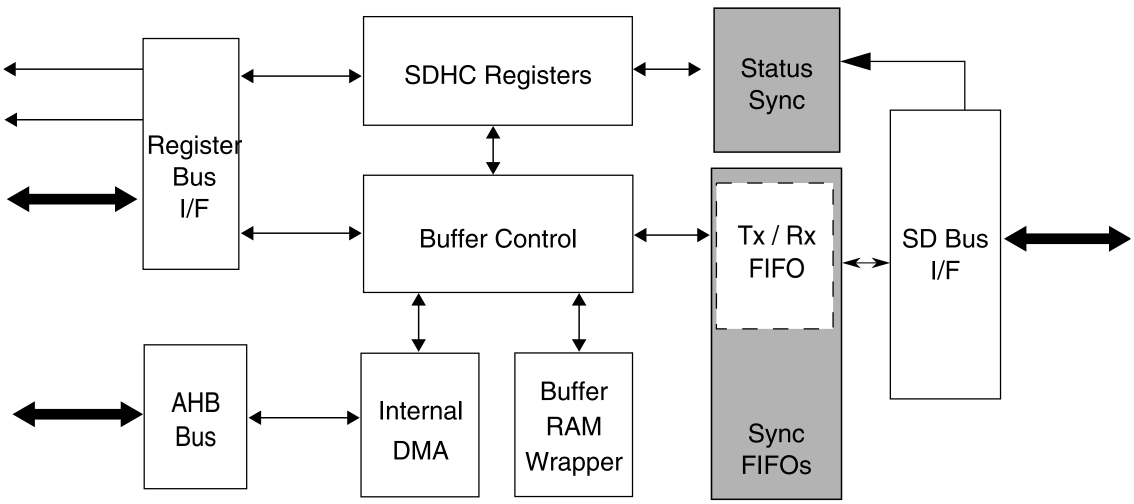

Figure 50-75. SDHC buffer scheme

There are 3 transfer modes to access the data buffer:

- CPU Polling mode:

    - For a host read operation, when the number of words received in the buffer meets or exceeds the RDWML watermark value, then by polling IRQSTAT[BRR] the host driver can read the DATPORT register to fetch the amount of words set in the WML register from the buffer. The write operation is similar.
- Internal DMA mode (includes simple and advanced DMA access's):
    - The internal DMA access, either by simple or advanced DMA, is over the crossbar switch bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in WML, the internal DMA starts fetching data over the crossbar switch bus. Except INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

1. Burst length configured in the burst length field of WML
2. Watermark level boundary
3. Block size boundary
4. Data boundary configured in the current descriptor if the ADMA is active
5. 1 KB address boundary

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actually byte order is swapped inside the buffer, according to the endian mode configured by software, as illustrated in the following diagrams. For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

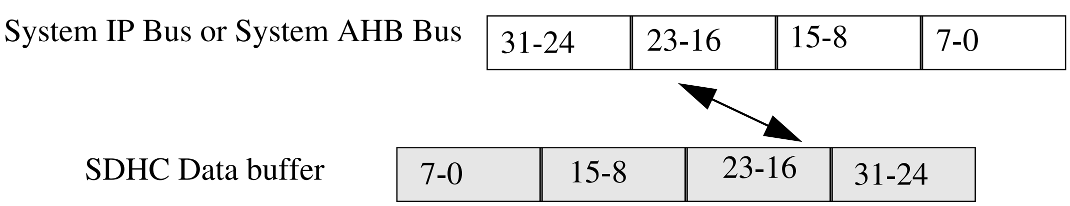

Figure 50-76. Data swap between system bus and SDHC data buffer in byte little endian mode

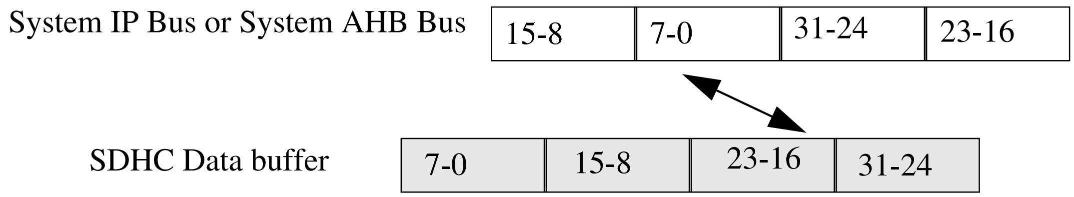

Figure 50-77. Data swap between system bus and SDHC data buffer in half word big endian mode

50.5.1.1 Write operation sequence

There are three ways to write data into the buffer when the user transfers data to the card:

1. Using external DMA through the SDHC DMA request signal.
2. Processor core polling through IRQSTAT[BWR] (interrupt or polling).
3. Using the internal DMA.

When the internal DMA is not used, that is, the XFERTYP[DMAEN] bit is not set when the command is sent, the SDHC asserts a DMA request when the amount of buffer space exceeds the value set in WML, and is ready for receiving new data. At the same time, the SDHC would set IRQSTAT[BWR]. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the SDHC will not inform the system before all the required number of bytes are transferred if no error was encountered. When an error occurs during the data transfer, the SDHC will abort the data transfer and abandon the current block. The host driver must read the contents of the DSADDR to get the starting address of the abandoned data block. If the current data transfer is in multiblock mode, the SDHC will not automatically send CMD12, even though XFERTYP[AC12EN] is set. The host driver shall send CMD12 in this scenario and restart the write operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

The SDHC will not start data transmission until the number of words set in WML can be held in the buffer. If the buffer is empty and the host system does not write data in time, the SDHC will stop the SD_CLK to avoid the data buffer underrun situation.

50.5.1.2 Read operation sequence

There are three ways to read data from the buffer when the user transfers data to the card:

1.

2. Processor core polling through IRQSTAT[BRR] (interrupt or polling)
3. Using the internal DMA

When internal DMA is not used, that is, XFERTYP[DMAEN] is not set when the command is sent, the SDHC asserts a DMA request when the amount of data exceeds the value set in WML, that is available and ready for system fetching data. At the same time, the SDHC would set IRQSTAT[BRR]. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the SDHC will not inform the system before all the required number of bytes are transferred if no error was encountered. When an error occurs during the data transfer, the SDHC will abort the data transfer and abandon the current block. The host driver must read the content of the DMA system address register to get the starting address of the abandoned data block. If the current data transfer is in multiblock mode, the SDHC will not automatically send CMD12, even though XFERTYP[AC12EN] is set. The host driver shall send CMD12 in this scenario and restart the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

For any write transfer mode, the SDHC will not start data transmission until the number of words set in WML are in the buffer. If the buffer is full and the Host System does not read data in time, the SDHC will stop the SDHC_DCLK to avoid the data buffer overrun situation.

50.5.1.3 Data buffer and block size

The user needs to know the buffer size for the buffer operation during a data transfer to use it in the most optimized way. In the SDHC, the only data buffer can hold up to 128 words (32-bit), and the watermark levels for write and read can be configured respectively. For both read and write, the watermark level can be from 1 word to the maximum of 128 words. For both read and write, the burst length can be from 1 word to the maximum of 31 words. The host driver may configure the value according to the system situation and requirement.

During a multiblock data transfer, the block length may be set to any value between 1 and 4096 bytes inclusive, which satisfies the requirements of the external card. The only restriction is from the external card. It might not support that large of a block or it doesn't support a partial block access, which is not the integer times of 512 bytes.

For block size not times of 4, that is, not word aligned, SDHC requires stuff bytes at the end of each block, because the SDHC treats each block individually. For example, the block size is 7 bytes, there are 12 blocks to write, the system side must write 2 times for

each block, and for each block, the ending byte would be abandoned by the SDHC because it sends only 7 bytes to the card and picks data from the following system write, so there would be 24 beats of write access in total.

50.5.1.4 Dividing large data transfer

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

The following diagram illustrates the dividing of large data transfers. Assuming a kind of WLAN SDIO card supports block size only up to 64 bytes. Although the SDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided. See the example below.

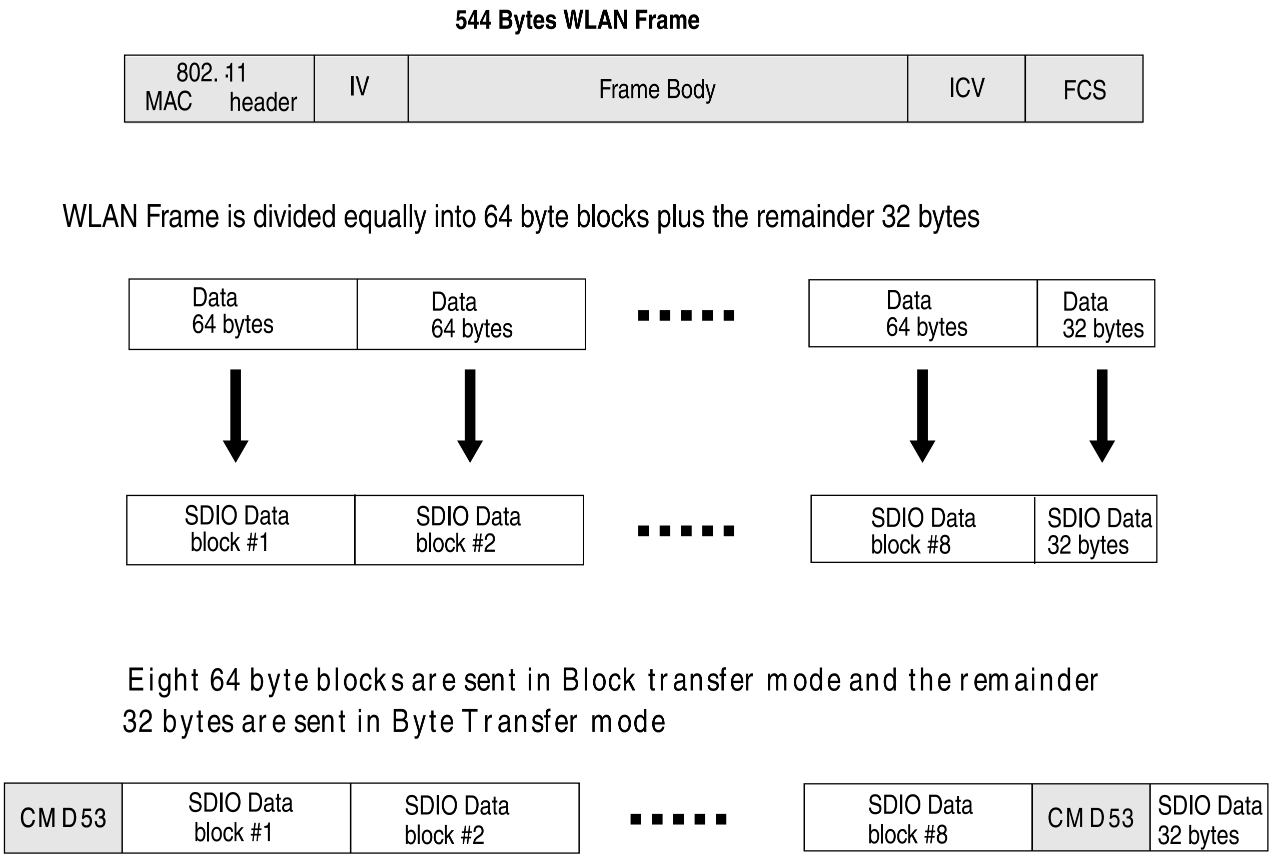

Figure 50-78. Example for dividing large data transfers

50.5.1.5 External DMA request

When the internal DMA is not in use, and external DMA request is enabled, the data buffer will generate a DMA request to the system. During a write operation, when the number of WRWML words can be held in the buffer free space, a DMA request is sent , informing the host system of a DMA write. IRQSTAT[BWR] is also set, as long as IRQSTATEN[BWRSEN] is set. The DMA request is immediately deasserted when an access to the DATPORT register is made. If the buffer's free space still meets the watermark condition, the DMA request is asserted again after a cycle.

On read operation, when the number of RDWML words are already in the buffer, a DMA request is sent, informing the host system for a DMA read. IRQSTAT[BRR] is also set, as long as IRQSTATEN[BRRSEN] is set. The DMA request is immediately deasserted when an access to the DATPORT register is made. If the buffer's data still meets the watermark condition, the DMA request is asserted again after a cycle.

Because the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring of the block may cause buffer underrun for read operation or overrun for

write operation. For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of 2 between 1 and 128. For processor core polling access, as the last access in the block transfer can be controlled by software, there is no such issue. The watermark level can be any value, even larger than the block size but not greater than 128 words. This is because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The SDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level must be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of word. For this case, the BLKATTR[BLKSIZE] bits shall be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the SDHC will also set the IRQSTAT[BWR] or IRQSTAT[BRR] bits when the remaining data does not violate data buffer. See DMA burst length for more details about the dynamic watermark level of the data buffer. For the above example, even though 8 words are transferred via the DATPORT register, the SDHC will transfer only 31 bytes over the SD bus, as required by the BLKATTR[BLKSIZE] bits. In this data transfer, with non-word aligned block size, the endian mode must be set cautiously, or invalid data will be transferred to/from the card.

50.5.2 DMA crossbar switch interface

The internal DMA implements a DMA engine and the crossbar switch master. When the internal DMA is enabled (XFERTYP[DMAEN] is set), the interrupt status bits are set if they are enabled. To avoid setting them, clear IRQSTATEN[BWRSEN, BRRSEN]. The following diagram illustrates the DMA crossbar switch interface block.

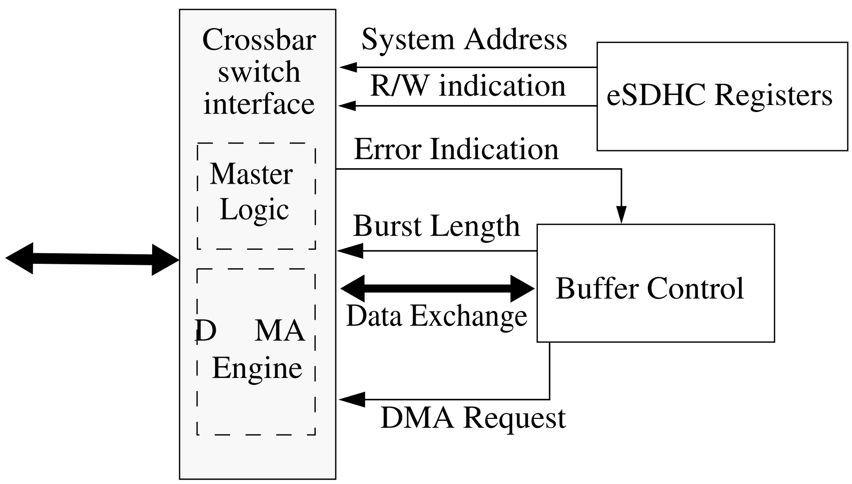

Figure 50-79. DMA crossbar switch interface block

50.5.2.1 Internal DMA request

If the watermark level requirement is met in data transfer, and the internal DMA is enabled, the data buffer block sends a DMA request to the crossbar switch interface. Meanwhile, the external DMA request signal is disabled. The delay in response from the internal DMA engine depends on the system bus loading and the priority assigned to the SDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request once an access to the buffer is made. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multiblock data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer, which might contain some data of the next block, another DMA request read is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The SDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuff byte.

50.5.2.2 DMA burst length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. Take the example in Internal DMA request again. The following burst length after 6 words are read will be 2 words, and the next burst length will be 6 words again. This is because the next block starts, which is 31 bytes, more than 6 words. The host driver writer may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

50.5.2.3 Crossbar switch master interface

It is possible that the internal DMA engine could fail during the data transfer. When this error occurs, the DMA engine stops the transfer and goes to the idle state as well as the internal data buffer stops accepting incoming data. IRQSTAT[DMAE] is set to inform the driver.

After the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read DSADDR[DSADDR] to get the starting address of the corrupted block. After the DMA error is fixed, the software must apply a data reset and restart the transfer from this address to recover the corrupted block.

50.5.2.4 ADMA engine

In the SDHC standard, the new DMA transfer algorithm called the advanced DMA (ADMA) is defined. For simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention would not be needed during long DMA-based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in host controller. ADMA1 can support data transfer of 4 KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of descriptor table are different.

ADMA can recognize all kinds of descriptors defined in the SDHC standard, and if end flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

50.5.2.4.1 ADMA concept and descriptor format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor
- Nop descriptor

- Rsv descriptor
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the Valid flag of descriptor is 0, it will ignore the high 32-bit. The address field shall be set on word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before tran type descriptor. Every tran type will trigger a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous trans descriptor, the data length will be the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, tran type descriptor contains both the data length and transfer data address, so only a tran type descriptor can start a data transfer.

Table 50-101. Format of the ADMA1 descriptor table

Address/page field		**Address/page field**		**Attribute field**					
31	12	11	6	5	4	3	2	1	0
Address or data length		000000		Act2	Act1	0	Int	End	Valid

Act2	**Act1**	**Symbol**	**Comment**	**31-28**	**27-12**
0	0	nop	No operation	Don't care	
0	1	set	Set data length	0000	Data length
1	0	tran	Transfer data	Data address	
1	1	link	Link descriptor	Descriptor address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA interrupt when this descriptor is processed.

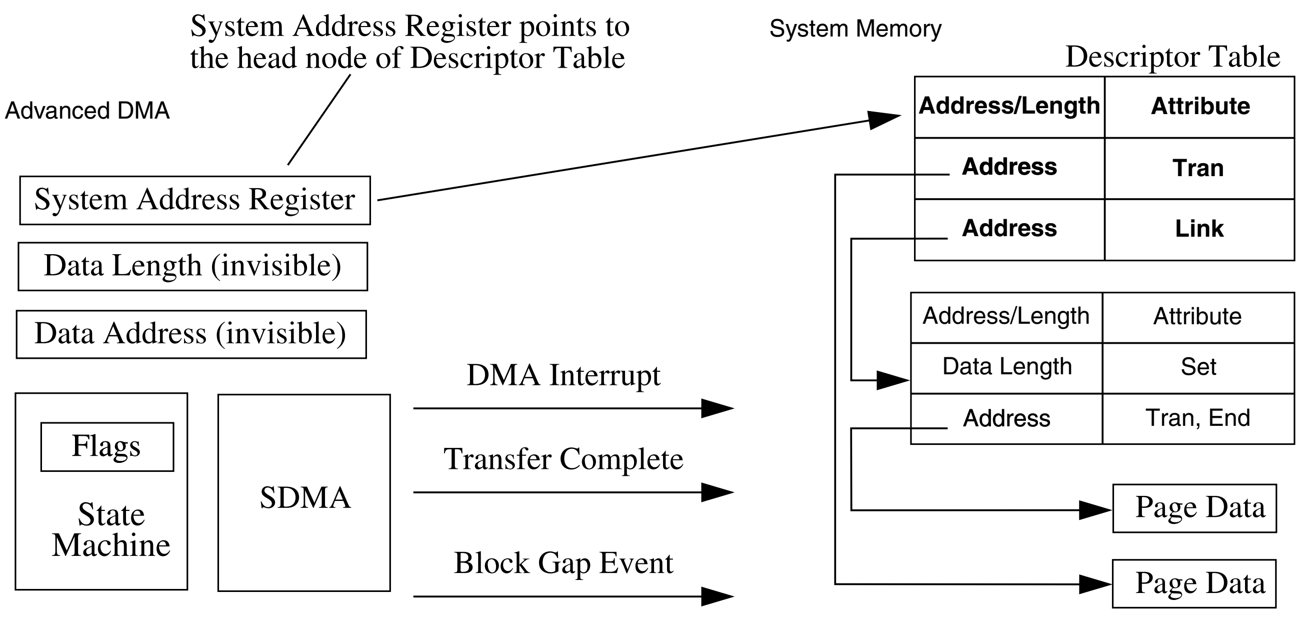

Figure 50-80. Concept and access method of ADMA1 descriptor table

Table 50-102. Format of the ADMA2 descriptor table

Address field		**Length**		**Reserved**			**Attribute field**				
63	32	31	16	15	06	05	04	03	02	01	00
32-bit address		16-bit length		0000000000		Act2	Act1	0	Int	End	Valid

Act2	**Act1**	**Symbol**	**Comment**	**Operation**
0	0	nop	No operation	Don't care
0	1	rsv	Reserved	Same as nop. Read this line and go to next one
1	0	tran	Transfer data	Transfer data with address and length set in this descriptor line
1	1	link	Link descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If valid = 0 generate ADMA error interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA interrupt when this descriptor is done.

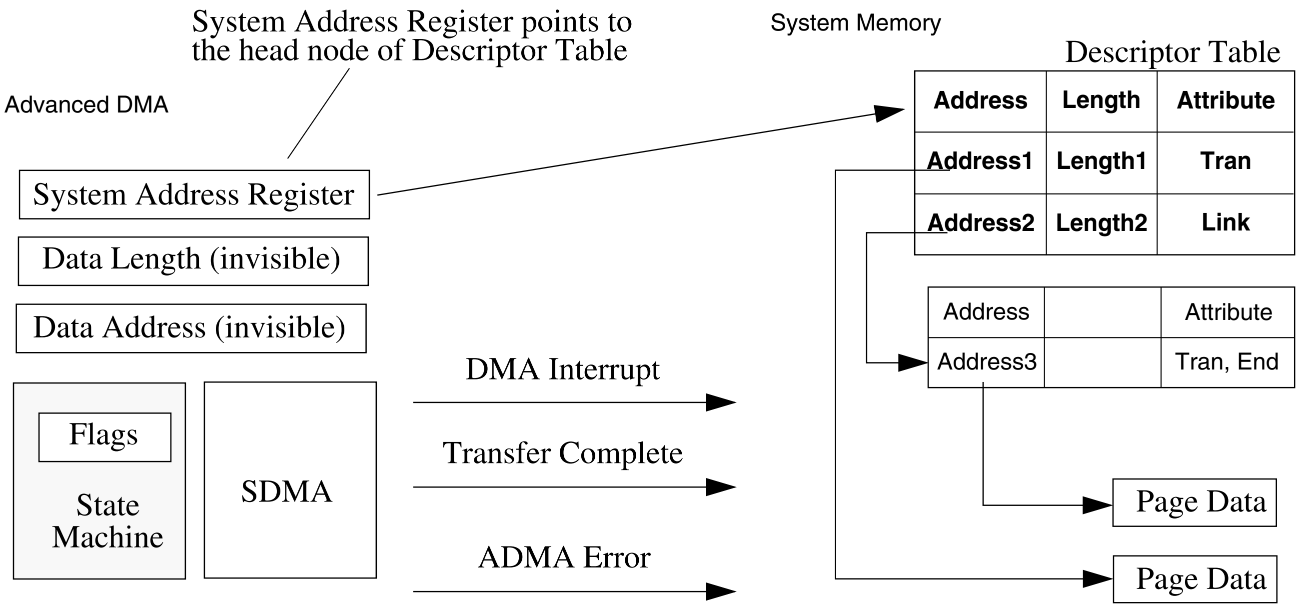

Figure 50-81. Concept and access method of ADMA2 descriptor table

50.5.2.4.2 ADMA interrupt

If the interrupt flag of descriptor is set, ADMA will generate an interrupt according to different type descriptor:

For ADMA1:

- Set type descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop type descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type descriptor: interrupt is generated just after fetch this descriptor.

50.5.2.4.3 ADMA error

The ADMA stops whenever any error is encountered. These errors include:

- Fetching descriptor error

- Transfer error
- Data length mismatch error

ADMA descriptor error will be generated when it fails to detect the valid flag in the descriptor. If ADMA descriptor error occurs, the interrupt is not generated even if the interrupt flag of this descriptor is set.

When XFERTYP[BCEN] is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

If XFERTYP[BCEN] is not set, the whole data length set in descriptor must be times of block length, otherwise, when all data set in the descriptor nodes are done not at block boundary, the data mismatch error will occur.

50.5.3 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into the corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD transceiver
- SD clock and monitor
- Command agent
- Data agent

50.5.3.1 SD transceiver

In the SD protocol unit, the transceiver is the main control module. It consists of a FSM and control module, from which the control signals for all other three modules are generated.

50.5.3.2 SD clock & monitor

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the register bank. The driver can use this for debug purposes.

The module also detects the card detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when PROCTL[D3CD] is set.

The module detects the write protect (WP) line. With the information of the WP state, the register bank will ignore the command, accompanied by a write operation, when the WP switch is on.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this module will open and the SD clock will be active again.

This module also drives the SDHC_LCTL output signal when PROCTL[LCTL] is set by the driver.

50.5.3.3 Command agent

The command agent deals with the transactions on the CMD line. The following diagram illustrates the structure for the command CRC Shift Register.

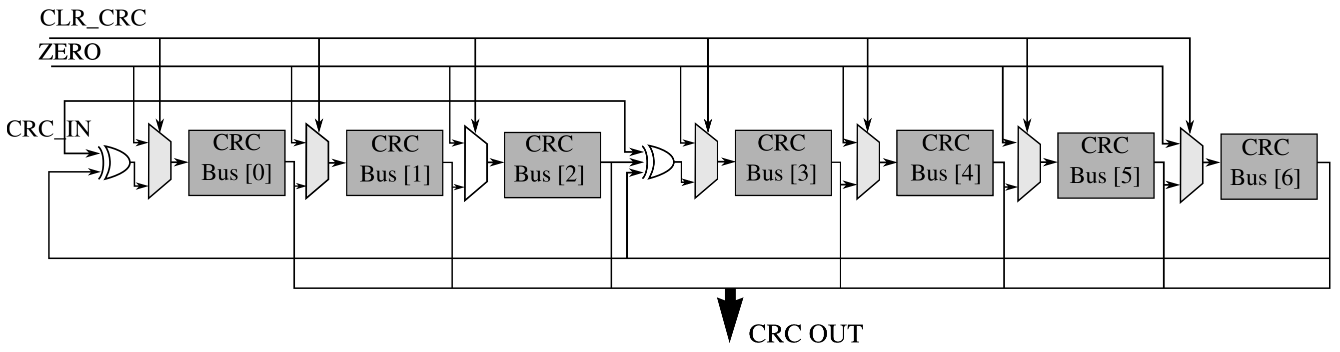

Figure 50-82. Command CRC Shift Register

The CRC polynomials for the CMD line are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} +...+ (\text{last bit}) * x^0$
$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$

50.5.3.4 Data agent

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DAT[0] line, and generates the read wait state by the request from the transceiver. The CRC polynomials for the DAT are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 +1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} +...+ (\text{last bit}) * x^0$
$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$

50.5.4 Clock and reset manager

This module controls all the reset signals within the SDHC.

There are four kinds of reset signals within the SDHC:

- Hardware reset
- Software reset for all
- Software reset for the data part
- Software reset for the command part

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

There are three clocks inside the SDHC:

- Bus clock
- SDHC clock
- System clock

The module monitors the activities of all other modules, supplies the clocks for them, and when enabled, automatically gates off the corresponding clocks.

50.5.5 Clock generator

The clock generator generates the SDHC_CLK by peripheral source clock in two stages. The following diagram illustrates the structure of the divider. The term "base" represents the frequency of peripheral source clock.

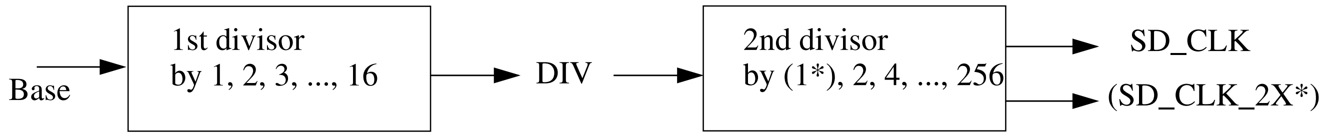

Figure 50-83. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV), which can be base, base/2, base/3, ..., or base/16.

The second stage is a prescaler, and outputs the actual clock (SDHC_CLK). This clock is the driving clock for all submodules of the SD protocol unit, and the sync FIFOs to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4,..., or DIV/256. Thus, the highest frequency of the SDHC_CLK is base, and the next highest is base/2, while the lowest frequency is base/4096. If the base clock is of equal duty ratio (usually true), the duty cycle of SDHC_CLK is also 50%, even when the compound divisor is an odd value.

50.5.6 SDIO card interrupt

This section discusses SDIO interrupt handling.

50.5.6.1 Interrupts in 1-bit mode

In this case, the DAT[1] pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

50.5.6.2 Interrupt in 4-bit mode

Because the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will be sent by the card and recognized by the host only during a specific time. This is known as the interrupt period. The SDHC will only sample the level on pin 8 during the interrupt period. At all other times, the host will ignore the level on pin 8, and treat it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the interrupt period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the interrupt period. In this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the SDHC_D1 line will be held low for one clock cycle with the last clock cycle pulling SDHC_D1 high. On completion of the Interrupt Period, the card releases the SDHC_D1 line into the high Z state. The SDHC samples the SDHC_D1] during the interrupt period when PROCTL[IABG] is set.

See the SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

50.5.6.3 Card interrupt handling

When IRQSIGEN[CINTIEN] is set to 0, the SDHC clears the interrupt request to the host system. The host driver must clear this bit before servicing the SDIO Interrupt and must set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the SDHC will detect the SDIO interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the host system interrupt controller. When the SDIO status has been set, and the host driver needs to service this interrupt, so the SDIO bit in the interrupt control register of the SDIO card will be cleared. This is required to clear the

SDIO interrupt status latched in the SDHC and to stop driving the interrupt signal to the system interrupt controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Enable bit is set to 1, and the SDHC starts sampling the interrupt signal again.

The following diagram illustrates the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

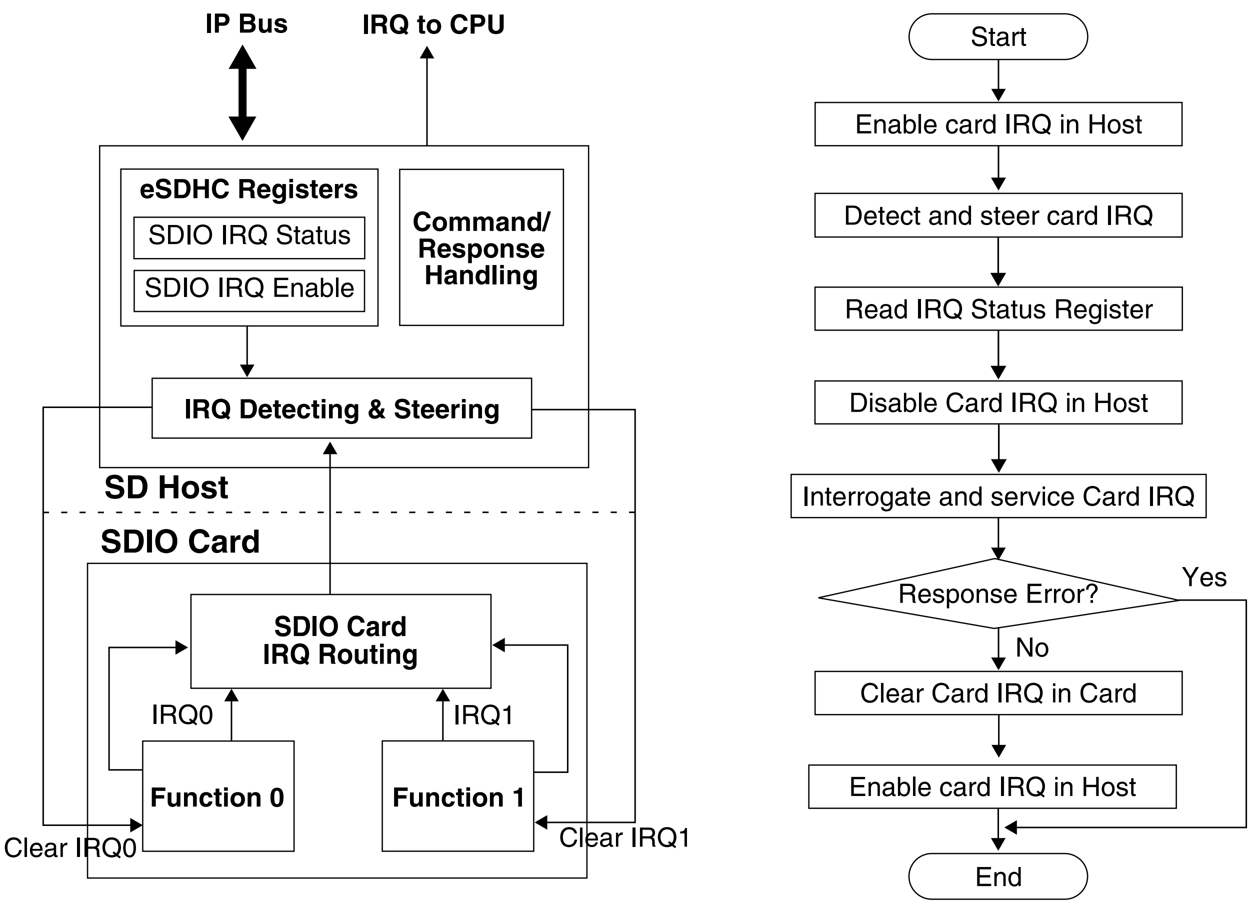

Figure 50-84. Card interrupt scheme and card interrupt detection and handling procedure

50.5.7 Card insertion and removal detection

The SDHC uses either the DAT[3] pin or the CD pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] will be pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the SDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card

detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the SDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

50.5.8 Power management and wakeup events

When there is no operation between the SDHC and the card through the SD bus, the user can completely disable the bus clock and the SDHC clock in the chip-level clock control module to save power. When the user needs to use the SDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the SDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The SDHC can generate these interrupt even when there are no clocks enabled.

The three interrupts which can be used as wakeup events are:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card

The SDHC offers a power management feature. By clearing the clock enabled bits in the system control register, the clocks are gated in the low position to the SDHC. For maximum power saving, the user can disable all the clocks to the SDHC when there is no operation in progress.

These three wakeup events, or wakeup interrupts, can also be used to wake up the system from low-power modes.

Note

To make the interrupt a wakeup event, when all the clocks to the SDHC are disabled or when the whole system is in low-power mode, the corresponding wakeup enabled bit needs to be set. See Protocol Control register for more information.

50.5.8.1 Setting wakeup events

For the SDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters Sleep mode. Before the software disables the host clock, it must ensure that all of the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

50.5.9 MMC fast boot

In Embedded MultiMediaCard(eMMC4.3) spec, add fast boot feature needs hardware support.

In Boot Operation mode, the master (multimediacard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

There are two types of Fast Boot mode, boot operation, and Alternative boot operation in eMMC4.3 spec. Each type also has with acknowledge and without acknowledge modes.

Note

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

50.5.9.1 Boot operation

Note

In this block guide, this fast boot is called Normal Fast Boot mode.

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that Boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes low, the slave starts to send the first boot data to the master on the DAT line(s). The master must keep the CMD line low to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern 010 to the master within 50 ms after the CMD line goes low. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate Boot mode with the CMD line high.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

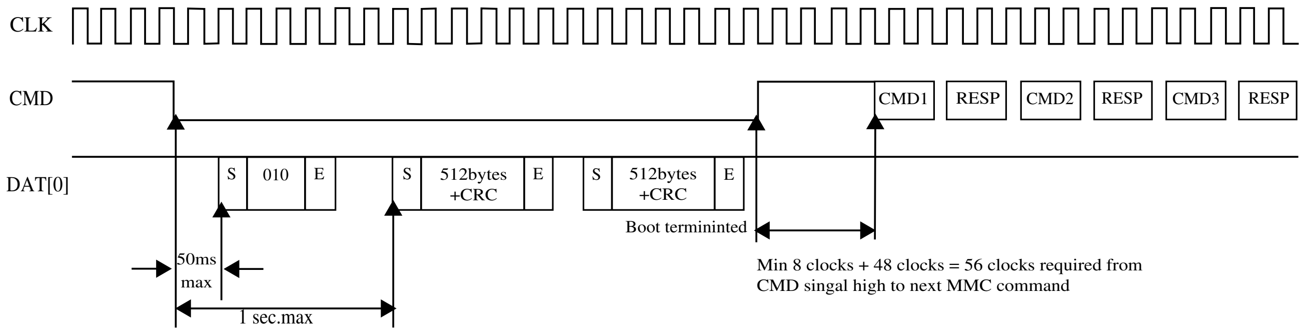

Figure 50-85. Multimediacard state diagram in Normal Boot mode

50.5.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to 1, the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued, or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DAT line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, theslave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

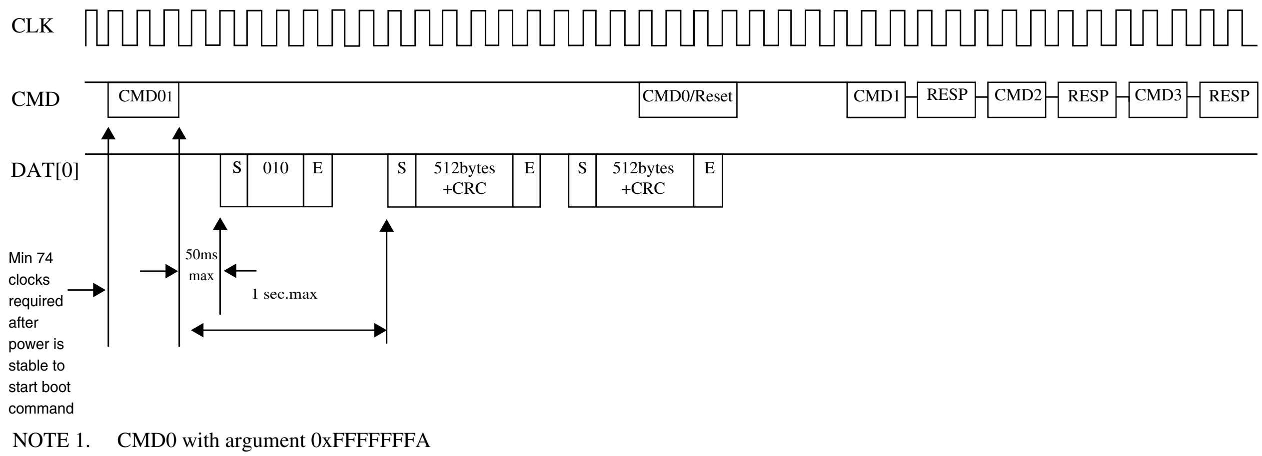

Figure 50-86. MultiMediaCard state diagram in Alternative Boot mode

50.6 Initialization/application of SDHC

All communication between system and cards are controlled by the host. The host sends commands of two types:

- Broadcast
- Addressed point-to-point

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, ALL_SEND_CID, and so on. In Broadcast mode, all cards are in the Open-Drain mode to avoid bus contention. See Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter Standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to Push-Pull mode, to have the driving capability for maximum frequency operation. See Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

50.6.1 Command send and response receive basic operation

Assuming the data type WORD is an unsigned 32-bit integer, the following flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
```

```
if (multi-block transfer) {
 set MSBSEL bit;
 if (finite block number) {
  set BCEN bit;
  if (auto12 command is to use) set AC12EN bit;
 }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the command complete interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

In some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the standby state, no response to the host when CMD2 is sent. The host driver shall deal with 'fake' errors like this with caution.

50.6.2 Card Identification mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the relative card address (RCA) or to set the RCA for the MMC cards.

50.6.2.1 Card detect

The following diagram illustrates the detection of MMC, SD, and SDIO cards using the SDHC.

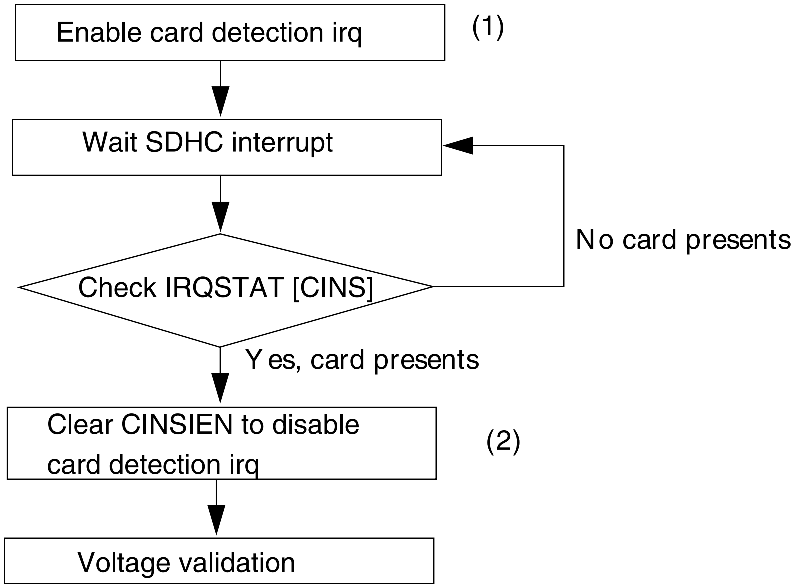

Figure 50-87. Flow diagram for card detection

Here is the card detection sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the SDHC is received, check IRQSTAT[CINS] in the Interrupt Status register to see whether it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

50.6.2.2 Reset

The host consists of three types of resets:

- Hardware reset (card and host) which is driven by power on reset (POR)
- Software reset (host only) is proceed by the write operation on the SYSCTL[RSTD], SYSCTL[RSTC], or SYSCTL[RSTA] bits to reset the data part, command part, or all parts of the host controller, respectively
- Card reset (card only). The command, Go_Idle_State (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the idle state regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA = 0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. The following diagram illustrates the software flow to reset both the SDHC and the card.

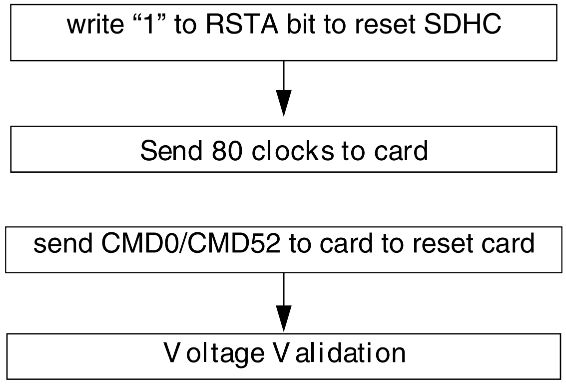

Figure 50-88. Flow chart for reset of the SDHC and SD I/O card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DTOCV and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

50.6.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for V_{DD} are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are able to communicate this information only under data transfer V_{DD} conditions. This means if the host and card have noncommon V_{DD} ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the V_{DD} range(s) desired by the host. This is accomplished by the host sending the desired V_{DD} voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before

sending out-of-range cards into the inactive state. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a nonusable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
 if (0 < number of IO functions) {
  label the card as SDIO;
  IORDY = 0;
  while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
   send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
   wait_for_response(IO_SEND_OP_COND);
  } // end of while ...
 } // end of if (0 < ...
 if (memory part is present inside SDIO card) Label the card as SDCombo; // this is an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
 send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range
for memory part or SD card
 wait_for_response(SD_APP_OP_COND); // voltage range is set
 if (card type is UNKNOWN) label the card as SD;
 return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
 deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card or CE-ATA card
 if (card is already labelled as SDCombo) { // change label
  re-label the card as SDIO;
  ignore the error or report it;
  return; // card is identified as SDIO card
 } // of if (card is ...
 send_command(SEND_OP_COND, <voltage range>, <...>);
 if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
  label the card as UNKNOWN;
  return;
 } // of if (RESP_TIMEOUT ...
 if (check for CE-ATA signature succeeded) { // the card is CE-ATA
  store CE-ATA specific info from the signature;
  label the card as CE-ATA;
 } // of if (check for CE-ATA ...
 else label the card as MMC;
} // of else
}
```

50.6.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different.

For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V, as defined by the card specification. At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified, in the ready state, send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in Open-Drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated, the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the wired OR operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state.

The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards, the cards in ready state, simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Because the CID is unique for each card, only one card can successfully send its full CID to the host. This card then goes into the Identification state.

Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). When the RCA is received the card state changes to the standby state, and the card does not react in further identification cycles, and its output driver

switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
 if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
  send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its
RCA
  retrieve RCA from response;
 } // end if (card is labelled as SDCombo ...
 else if (card is labelled as SD) { // for SD card
  send_command(ALL_SEND_CID, <...>);
  if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
  send_command(SET_RELATIVE_ADDR, <...>);
  retrieve RCA from response;
 } // else if (card is labelled as SD ...
 else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
  send_command(ALL_SEND_CID, <...>);
  rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also the
relative address to access the CE-ATA card
  send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16
bits
 } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

50.6.3 Card access

This section discusses the various card access methods.

50.6.3.1 Block write

This section discusses the block write access methods.

50.6.3.1.1 Normal write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the dat line. The transferred data will be discarded and not written, and all further transmitted blocks in Multiple Block Write mode will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in

the status register, and while ignoring all further data transfer, waits in the Receive-Data-state for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 to select a different card to place the card into the Standby state and release the DAT line without interrupting the write operation. When reselecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods, by means of external DMA or CPU polling status, with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
    a. For SD/MMC cards, use SET_BLOCKLEN (CMD16)
    b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).

5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the eSDHC DMA when sending the command with data transfer. AC12EN should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see whether a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

50.6.3.1.2 Write with pause

The write operation can be paused during the transfer. Instead of stopping the SD_CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set PROCTL[SABGREQ] to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to deassert to release the busy state, no suspend command is needed.

Like the flow described in Normal write, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
    a. For SD/MMC, use SET_BLOCKLEN (CMD16)
    b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the SDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the SDHC DMA when sending the command with data transfer. The XFERTYP[AC12EN] bit should also be set.
6. Set PROCTL[SABGREQ].
7. Wait for the transfer complete interrupt.
8. Clear PROCTL[SABGREQ].
9. Check the status bit to see whether a write CRC error occurred.

10. Set PROCTL[CREQ] to continue the write operation.
11. Wait for the transfer complete interrupt.
12. Check the status bit to see whether a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKATTR[BLKCNT] . As the data transfer and the setting of the PROCTL[SABGREQ] bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The driver shall read the value of BLKATTR[BLKCNT] after the transfer is paused and the transfer complete interrupt is received.

It is also possible that the last block has begun when the stop at block gap request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the suspend command for the SDIO card. This is because when such a command is sent, the SDHC thinks the system will switch to another function on the SDIO card, and flush the data buffer. The SDHC takes the resume command as a normal command with data transfer, and it is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, XFERTYP[MSBSEL] and XFERTYP[BCEN] are set as well as XFERTYP[AC12EN]. However, the SDHC will automatically send a CMD12 to mark the end of the multiblock transfer.

50.6.3.2 Block read

This section discusses the block read access methods.

50.6.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the SDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the SDHC DMA when sending the command with data transfer. XFERTYP[AC12EN] must also be set.
6. Wait for the transfer complete interrupt.
7. Check the status bit to see whether a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

50.6.3.2.2 Read with pause

The read operation is not generally able to pause. Only the SDIO card and SDCombo card working under I/O mode supporting the read and wait feature can pause during the read operation. If the SDIO card support read wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the eSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. Set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Like the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set RWCTL.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
    a. For SD/MMC, use SET_BLOCKLEN (CMD16)
    b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
5. Set the SDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the SDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the eSDHC DMA when sending the command with data transfer. AC12EN must also be set.
8. Set SABGREQ.
9. Wait for the Transfer Complete interrupt.
10. Clear SABGREQ.
11. Check the status bit to see whether read CRC error occurred.
12. Set CREQ to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see whether a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the SDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. Whether the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the SDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the SDHC will automatically send the CMD12 to mark the end of multi-block transfer.

50.6.3.3 Suspend resume

The SDHC supports the suspend resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

50.6.3.3.1 Suspend

After setting the PROCTL[SABGREQ] bit, the host driver may send a suspend command to switch to another function of the SDIO card. The SDHC does not monitor the content of the response, therefore it doesn't know whether the suspend command succeeded or not. Accordingly, it doesn't deassert read wait for read pause. To solve this problem, the driver shall not mark the suspend command as a suspend, that is, setting the XFERTYP[CMDTYP] bits to 01. Instead, the driver shall send this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the driver send another command marked as suspend to inform the SDHC that the current transfer is suspended. As shown in the following sequence for suspend operation:

1. Set PROCTL[SABGREQ] to pause the current data transfer at block gap.
2. After IRQSTAT[BGE] is set, send the suspend command to suspend the active function. XFERTYP[CMDTYP] field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The XFERTYP[CMDTYP] of this command must be 2'b01, so the SDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the SDHC stops driving DAT2 and goes to the Idle state.
5. Save the context registers in the system memory for later use, including the DMA system address register for internal DMA operation, and the block attribute register.

6. Begin operation for another function on the SDIO card.

50.6.3.3.2 Resume

To resume the data transfer, a resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step 5 of the suspend operation above.
2. Send the resume command. In the transfer type register, all fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume, except the CMDTYP is set to 2'b10.
3. If the resume command has responded, the data transfer will be resumed.

50.6.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4 KB address aligned).
3. If necessary, create a link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1–3.
4. Repeat steps 1–3 until all descriptors are created.
5. In the last descriptor, set the end flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the BLKATTR register.
6. Set the DSADDR register to the address of the first descriptor and set the PROCTL[DMAS] field to 01 to select the ADMA.
7. Issue a write or read command with XFERTYP[DMAEN] set to 1.

Steps 1–5 are independent of step 6, so step 6 can finish before steps 1–5. Regarding the descriptor configuration, do not to use the link descriptor, as it requires extra system memory access.

50.6.3.5 Transfer error

This section discusses the handling of transfer errors.

50.6.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. Discard the following data blocks and retransfer the block from the corrupted one.

For a multi-block transfer, the host driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the XFERTYP[AC12EN] and BCEND bits are set, the SDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an auto CMD12 will be sent by the SDHC. In this case, the driver shall re-send or re-obtain the last block with a single block transfer.

50.6.3.5.2 Internal DMA error

During the data transfer with internal simple DMA, if the DMA engine encounters some error on the system bus, the DMA operation is aborted and DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the driver shall calculate the start address of data block in which the error occurs. The start address can be calculated by either:

1. Reading the DMA system address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Reading the BLKCNT field of the block attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the block attribute register does not change, so this method does not work.

When a DMA error occurs, abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

50.6.3.5.3 ADMA error

There are three kinds of possible ADMA errors: transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and retransfer from the place of interruption.

- Transfer error: May occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
- Invalid descriptor error: For such errors, retrieve the transfer context, reset for the data part, and recreate the descriptor chain from the invalid descriptor, and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The host driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

50.6.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and XFERTYP[AC12EN] is set when the data transfer is initiated by the data command, the SDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, the driver can deal with the situations in the following manner:

1. Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The driver should clear the IRQSTAT[AC12E] bits and resend the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error: Because the card responds to the CMD12, the card will abort the transfer. The driver may ignore the error and clear the IRQSTAT[AC12E] bit.
3. Auto CMD12 conflict error or not sent: The command is not sent, so the driver shall send a CMD12 manually.

50.6.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. The SDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the SDHC, and the host system is informed by the SDHC asserting the SDHC interrupt line, the interrupt service from the host driver is called.

Because the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before IRQSTAT[CINT] is cleared by written 1. See Card interrupt handling for the card interrupt handling flow.

50.6.4 Switch function

MMC cards transferring data at bus widths other than 1-bit is a new feature added to the MMC specifications. The high-speed timing mode for all card devices was also recently defined in various card specifications. To enable these new features, a switch command shall be issued by the host driver.

For SDIO cards, the high-speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6, with the mnemonic symbol as SWITCH_FUNC. For MMC cards , the high-speed mode is queried by a CMD8 and enabled by a CMD6, with the mnemonic symbol as SWITCH.

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

50.6.4.1 Query, enabl,e and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
```

```
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

50.6.4.2 Query, enable, and disable SD high-speed mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

50.6.4.3 Query, enable, and disable MMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
```

```
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

50.6.4.4 Set MMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

50.6.5 ADMA operation

This section presents code examples for ADMA operation.

50.6.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
      if (to start data transfer) {
          // Make sure the address is 4KB align.
          Set 'Set' type descriptor;
          {
              Set Act bits to 01;
              Set [31:12] bits data length (byte unit);
          }
          Set 'Tran' type descriptor;
          {
              Set Act bits to 10;
              Set [31:12] bits address (4KB align);
          }
      }
      else if (to fetch descriptor at non-continuous address) {
          Set Act bits to 11;
          Set [31:12] bits the next descriptor address (4KB align);
      }
      else { // other types of descriptor
          Set Act bits accordingly
      }
```

```
      if (this descriptor is the last one) {
          Set End bit to 1;
      }
      if (to generate interrupt for this descriptor) {
          Set Int bit to 1;
      }
      Set Valid bit to 1;
}
```

50.6.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
      if (to start data transfer) {
          // Make sure the address is 32-bit boundary (lower 2-bit are always '00').
          Set higher 32-bit of descriptor for this data transfer initial address;
          Set [31:16] bits data length (byte unit);
          Set Act bits to '10';
      }
      else if (to fetch descriptor at non-continuous address) {
          Set Act bits to '11';
          // Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
          Set higher 32-bit of descriptor for the next descriptor address;
      }
      else { // other types of descriptor
          Set Act bits accordingly
      }
      if (this descriptor is the last one) {
          Set 'End' bit '1';
      }
      if (to generate interrupt for this descriptor) {
          Set 'Int' bit '1';
      }
      Set the 'Valid' bit to '1';
}
```

50.6.6 Fast boot operation

This section discusses fast boot operations.

50.6.6.1 Normal fast boot flow

1. Software needs to configure SYSCTL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT[BOOTEN] to 1, MMCBOOT[BOOTMODE] to 0, and MMCBOOT[BOOTACK] to select the ack mode or not. If sending through DMA mode, software needs to configure MMCBOOT[AUTOSABGEN] to enable automatically stop at block gap feature, and MMCBOOT[DTOCVACK] to select the ack timeout value according to the sd clk frequence.

3. Software then needs to configure BLKATTR register to set block size/no.
4. Software needs to configure PROCTL[DTW].
5. Software needs to configure CMDARG to set argument if needed (no need in normal fast boot).
6. Software needs to configure XFERTYP register to start the boot process. In Normal Boot mode, XFERTYP[CMDINX], XFERTYP[CMDTYP], XFERTYP[RSPTYP], XFERTYP[CICEN], XFERTYP[CCCEN], XFERTYP[AC12EN], XFERTYP[BCEN] and XFERTYP[DMAEN] are kept default value. XFERTYP[DPSEL] bit is set to 1, XFERTYP[DTDSEL] is set to 1, XFERTYP[MSBSEL] is set to 1. Note XFERTYP[DMAEN] must be configured as 0 in polling mode. And if XFERTYP[BCEN] is configured as 1, better to configure BLKATTR[BLKSIZE] to the max value.
7. When the step 6 is configured, boot process will begin. Software needs to poll the data buffer ready status to read the data from buffer in time. If boot time-out happened (ack time out or the first data read time out), Interrupt will be triggered, and software need to configure MMCBOOT[]BOOTEN] to 0 to disable boot. Thus will make CMD high, and then after at least 56 clocks, it is ready to begin normal initialization process.
8. If no time out, software needs to decide the data read is finished and then configure MMCBOOT[]BOOTEN] to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
9. Reset the host and then can begin the normal process.

50.6.6.2 Alternative fast boot flow

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT [BOOTEN] to 1, MMCBOOT [BOOTMODE] to 1, and MMCBOOT [BOOTACK] to select the ack mode or not. If sending through DMA mode, it also needs to configure MMCBOOT [AUTOSABGEN] to enable automatically stop at block gap feature. And needs to configure MMCBOOT [DTOCVACK] to select the ack timeout value according to the sd clk frequence.
3. Software then needs to configure BLKATTR register to set block size/no.

4. Software needs to configure PROCTL[DTW].
5. Software needs to configure CMDARG register to set argument to 0xFFFFFFFA.
6. Software needs to configure XFERTYP register to start the boot process by CMD0 with 0xFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in Polling mode, it is better to configure blk no in Bock Attributes Register to the max value.
7. When step 6 is configured, boot process will begin. Software needs to poll the data buffer ready status to read the data from buffer in time. If boot time out (ack data time out in 50ms or data time out in 1s), host will send out the interrupt and software need to send CMD0 with reset and then configure boot enable bit to 0 to stop this process. After command completed, configure MMCBOOT[BOOTEN] to 0 to disable boot. After at least 8 clocks from command completed, card is ready for identification step.
8. If no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after command completed, configure MMCBOOT[BOOTEN] to stop the process. After 8 clocks from command completed, slave(card) is ready for identification step.
9. Reset the host and then begin the normal process.

50.6.6.3 Fast boot application case in DMA mode

In the boot application case, because the image destination and the image size are contained in the beginning of the image, switching DMA parameters on the fly during MMC fast boot is required.

In fast boot, host can use ADMA2 (advanced DMA2) with two destinations.

The detail flow:

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMCBOOT[BOOTEN] to 1; and MMCBOOT[BOOTMODE] to 0 (normal fast boot), to 1(alternative boot); and MMCBOOT[BOOTACK] to select the ack mode or not. In DMA mode, configure MMCBOOT[AUTOSABGEN] to 1 for enable automatically stop at block gap feature. Also configure MMCBOOT[BOOTBLKCNT] to set the VAULE1 (value of

block count that need to trans first time), so that host will stop at block gap when card block counter is equal to this value. And it needs to configure MMCBOOT[DTOCVACK] to select the ack timeout value according to the sd clk frequence.

3. Software then needs to configure BLKATTR register to set block size/no. In DMA mode, it is better to set block number to the max value(16'hffff).
4. Software needs to configure PROCTL[DTW].
5. Software enables ADMA2 by configuring PROCTL[DMAS].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (that is, in IRAM, at least 6 words). The first pair descriptor define the start address (IRAM) and data length(512byte*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writable), data length is suggest to set 1~2 word (record as VAULE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data_length data transfer descriptor.
7. Software needs to configure CMDARG register to set argument to 0xFFFFFFFA in alternative fast boot, and doesn't need to be set in normal fast boot.
8. Software needs to configure XFERTYP register to start the boot process . XFERTYP[CMDINX], XFERTYP[CMDTYP], XFERTYP[RSPTYP], XFERTYP[CICEN], XFERTYP[CCCEN], XFERTYP[AC12EN], XFERTYP[BCEN], and XFERTYP[DMAEN] are kept at default value. XFERTYP[DPSEL] bit is set to 1, XFERTYP[DTDSEL] is set to 1, XFERTYP[MSBSEL] is set to 1. XFERTYP[DMAEN] is configured as 1 in DMA mode. And if XFERTYP[BCEN] is configured as 1, better to configure blk no in BLKATTR register to the max value.
9. When step 8 is configured, boot process will begin, the first VAULE1 block number data has transfer. Software needs to poll IRQSTAT[TC] bit to determine first transfer is end. Also software needs to poll IRQSTAT[BGE] bit to determine if first transfer stop at block gap.
10. When IRQSTAT[TC] and IRQSTAT[BGE] bits are 1, . SW can analyzes the first code of VAULE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code (VAULE3 the remain boot code block). Remember set the last descriptor with END.
11. Software needs to configure MMCBOOT register (offset 0xc4) again. Set MMCBOOT[BOOTEN] bit to 1; and MMCBOOT[BOOTMODE] bit to 0 (normal fast boot), to 1 (alternative boot); and MMCBOOT[BOOTACK] bit to select the ack

mode or not. In DMA mode, configure MMCBOOT[AUTOSABGEN] bit to 1 for enable automatically stop at block gap feature. Also configure MMCBOOT[BOOTBLKCNT] bit to set the (VAULE1+1+VAULE3), so that host will stop at block gap when card block counter is equal to this value. And need to configure MMCBOOT[DTOCVACK] bit to select the ack timeout value according to the sd clk frequence.

12. Software needs to clear IRQSTAT[TC] and IRQSTAT[BGE] bit. And software need to clear PROCTL[SABGREQ], and set PROCTL[CREQ] to 1 to resume the data transfer. Host will transfer the VALUE2 and VAULE3 data to the destination that is set by descriptor.
13. Software needs to poll IRQSTAT[BGE] bit to determine if the fast boot is over.

Note

1. When ADMA boot flow is started, for SDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 words data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

50.6.7 Commands for MMC/SD/SDIO

The following table lists the commands for the MMC/SD/SDIO cards.

See the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the Multimediacard:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DAT
- Addressed (point-to-point) data transfer commands (adtc)

Table 50-103. Commands for MMC/SD/SDIO cards

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.

Table continues on the next page...

Table 50-103. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.

Table continues on the next page...

Table 50-103. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP _START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP _END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GRO UP	Removes one previously selected erase group from the erase selection.

Table continues on the next page...

Table 50-103. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57~59	Reserved				

Table continues on the next page...

Table 50-103. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62~63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[5]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD memory card status.
ACMD22[6]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[7]	ac		R1	SET_WR_BLK_ERASE_COUNT	-
ACMD41[8]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[9]	ac		R1	SET_CLR_CARD_DETECT	-
ACMD51[10]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards . The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 50-104.
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
5. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
6. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
7. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

8. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
9. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).
10. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT_CSD Access Modes are shown in the following table.

Table 50-104. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

50.7 Software restrictions

Software for the SDHC must observe the following restrictions.

50.7.1 Initialization active

The driver cannot set SYSCTL[INITA] when any of the command line or data lines is active, so the driver must ensure both PRSSTAT[CDIHB] and PRSSTAT[CIHB] bits are cleared. To auto clear SYSCTL[INITA], SYSCTL[SDCLKEN] must be 1, otherwise no clocks can go out to the card and SYSCTL[INITA] will never clear.

50.7.2 Software polling procedure

For polling read or write, when the software begins a buffer read or write, it must access exactly the number of times as the values set in the watermark level register. Moreover, if the block size is not the times of the value in watermark level register, read and write respectively, the software must access exactly the remained number of words at the end of each block.

For example, for read operation, if the WML[RDWML] is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

50.7.3 Suspend operation

To suspend the data transfer, the software must inform SDHC that the suspend command is successfully accepted. To achieve this, after the suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (XFERTYP[CMDTYP] bits set as 01) to inform SDHC that the transfer is suspended.

If software needs resume the suspended transfer, it should read the value in BLKATTR[BLKCNT] to save the remained number of blocks before sending the normal command marked as suspend, otherwise on sending such suspend command, SDHC will regard the current transfer as aborted and change BLKATTR[BLKCNT] to its original value, instead of keeping the remained number of blocks.

50.7.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be times of 4.

50.7.5 (A)DMA address setting

To configure ADMA1/ADMA2/DMA address register, when TC[IRQSTAT] is set, the register will always update itself with the internal address value to support dynamic address synchronization, so software must ensure that TC[IRQSTAT] is cleared prior to configuring ADMA1/ADMA2/DMA address register.

50.7.6 Data port access

Data port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or external DMA. Otherwise the data would be corrupted inside the SDHC buffer.

50.7.7 Change clock frequency

SDHC does not automatically gates off the card clock when the host driver changes the clock frequency. To remove possible glitch on the card clock, clear SYSCTL[SDCLKEN] when changing clock divisor value and set SYSCTL[SDCLKEN] to 1 after PRSSTAT[SDSTB] is 1 again.

50.7.8 Multi-block read

For predefined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or predefined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by SDHC after the pre-defined number of blocks are done, to drive the internal start response timeout. Manually sending an abort command with XFERTYP[RSPTYP] both bits cleared is recommended.

Chapter 51
Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI)

51.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The I^2S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I^2S, AC97, TDM, and codec/DSP interfaces.

51.1.1 Features

- Transmitter with independent bit clock and frame sync supporting 1 data channel
- Receiver with independent bit clock and frame sync supporting 1 data channel
- Maximum Frame Size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 32 × 32-bit FIFO for each transmit and receive channel
- Supports graceful restart after FIFO error

51.1.2 Block diagram

The following block diagram also shows the module clocks.

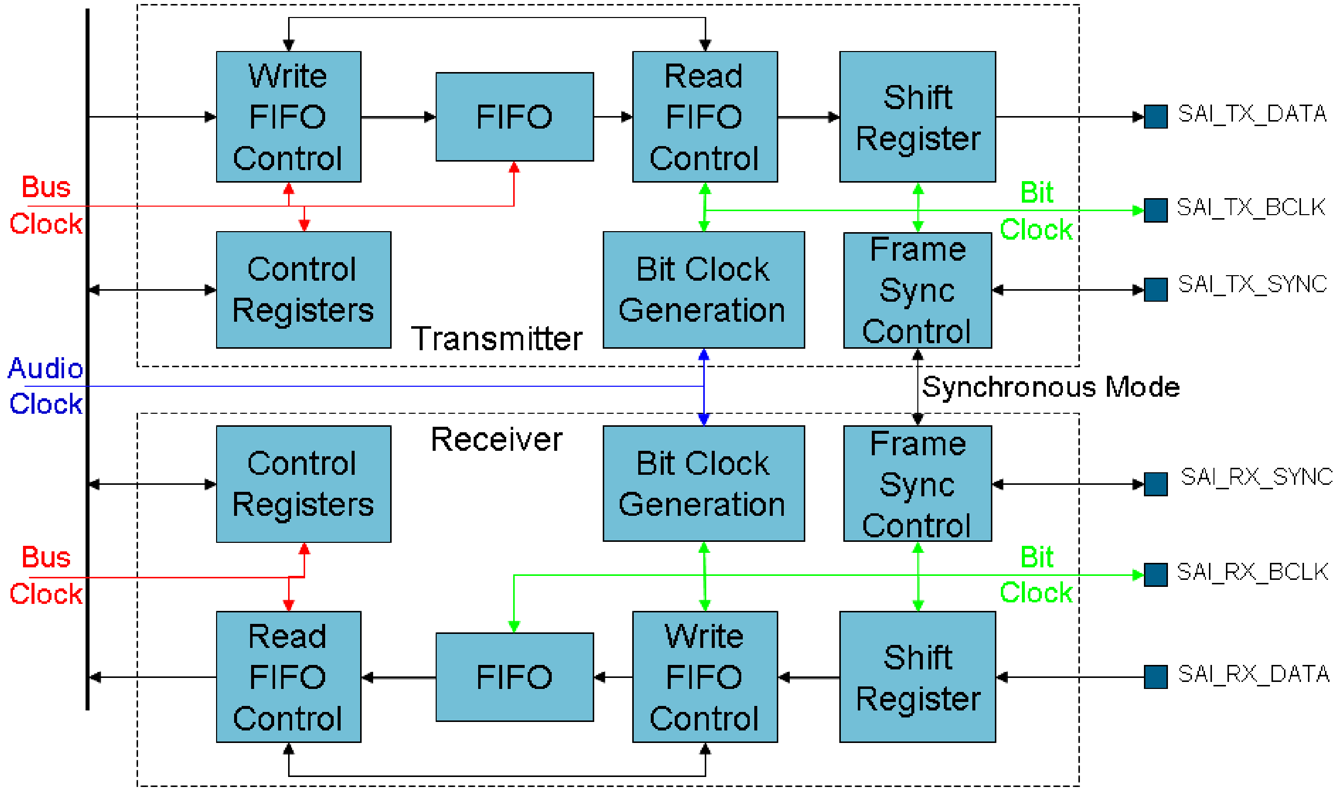

Figure 51-1. I²S/SAI block diagram

51.1.3 Modes of operation

The module operates in these MCU power modes: Run mode, stop modes, and Debug mode.

51.1.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

51.1.3.2 Stop modes

In Stop mode, the transmitter is disabled after completing the current transmit frame, and, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented–not acknowledged–while waiting for the transmitter and receiver to be disabled at the end of the current frame.

51.1.3.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

51.2 External signals

Name	Function	I/O	Reset	Pull
SAI_TX_BCLK	Transmit Bit Clock	I/O	0	—
SAI_TX_SYNC	Transmit Frame Sync	I/O	0	—
SAI_TX_DATA	Transmit Data	O	0	—
SAI_RX_BCLK	Receive Bit Clock	I/O	0	—
SAI_RX_SYNC	Receive Frame Sync	I/O	0	—
SAI_RX_DATA	Receive Data	I	0	—
SAI_MCLK	Audio Master Clock	I	0	—

51.3 Memory map and register definition

A read or write access to an address after the last register will result in a bus error.

I2S memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4002_F000	SAI Transmit Control Register (I2S0_TCSR)	32	R/W	0000_0000h	51.3.1/2851

I2Sx_TCSR field descriptions

Field	Description
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0 Transmitter is disabled. 1 Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures transmitter operation in Stop mode. This field is ignored and the transmitter is disabled in all stop modes. 0 Transmitter disabled in Stop mode. 1 Transmitter enabled in Stop mode.
29 DBGE	Debug Enable

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
	Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0 Transmitter is disabled in Debug mode, after completing the current frame. 1 Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0 Transmit bit clock is disabled. 1 Transmit bit clock is enabled.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 FR	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0 No effect. 1 FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0 No effect. 1 Software reset.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0 Start of word not detected. 1 Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 Sync error not detected. 1 Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0 Transmit underrun not detected. 1 Transmit underrun detected.

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0 No enabled transmit FIFO is empty. 1 Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0 Transmit FIFO watermark has not been reached. 1 Transmit FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FWDE	FIFO Warning DMA Enable

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
	Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.

51.3.2 SAI Transmit Configuration 1 Register (I2Sx_TCR1)

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	0								DIV							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_TCR2 field descriptions

Field	Description
31–30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation. 00 Asynchronous mode. 01 Synchronous with receiver. 10 Synchronous with another SAI transmitter. 11 Synchronous with another SAI receiver.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC). 0 Use the normal bit clock source. 1 Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.
27–26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip configuration details for the availability and chip-specific meaning of each option. 00 Bus Clock selected. 01 Master Clock (MCLK) 1 option selected. 10 Master Clock (MCLK) 2 option selected. 11 Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.

Table continues on the next page...

I2Sx_TCR2 field descriptions (continued)

Field	Description
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 Bit clock is generated externally in Slave mode. 1 Bit clock is generated internally in Master mode.
23–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

51.3.4 SAI Transmit Configuration 3 Register (I2Sx_TCR3)

This register must not be altered when TCSR[TE] is set.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								0							TCE
W

I2Sx_TCR3 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operation. A channel must be enabled before its FIFO is accessed. 0 Transmit data channel N is disabled. 1 Transmit data channel N is enabled.
15–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

I2Sx_TCR3 field descriptions (continued)

Field	Description
4–0 WDFL	Word Flag Configuration Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

51.3.5 SAI Transmit Configuration 4 Register (I2Sx_TCR4)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

I2Sx_TCR4 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.

Table continues on the next page...

I2Sx_TCR4 field descriptions (continued)

Field	Description
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0 LSB is transmitted first. 1 MSB is transmitted first.
3 FSE	Frame Sync Early 0 Frame sync asserts with the first bit of the frame. 1 Frame sync asserts one bit before the first bit of the frame.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 Frame sync is active high. 1 Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 Frame sync is generated externally in Slave mode. 1 Frame sync is generated internally in Master mode.

51.3.6 SAI Transmit Configuration 5 Register (I2Sx_TCR5)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

I2Sx_TCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.

Table continues on the next page...

I2Sx_TCR5 field descriptions (continued)

Field	Description
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
7–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.3.7 SAI Transmit Data Register (I2Sx_TDR*n*)

Address: Base address + 20h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0

I2Sx_TDR*n* field descriptions

Field	Description
31–0 TDR[31:0]	Transmit Data Register The corresponding TCR3[TCE] bit must be set before accessing the channel's transmit data register. Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

51.3.8 SAI Transmit FIFO Register (I2Sx_TFR*n*)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + 40h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

I2Sx_TFR*n* field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
15–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–0 RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.

51.3.9 SAI Transmit Mask Register (I2Sx_TMR)

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

I2Sx_RCR2 field descriptions

Field	Description
31–30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter must be configured for asynchronous operation. 00 Asynchronous mode. 01 Synchronous with transmitter. 10 Synchronous with another SAI receiver. 11 Synchronous with another SAI transmitter.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (SAI_TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (SAI_RX_SYNC). When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (SAI_RX_BCLK) but use the transmitter frame sync (SAI_TX_SYNC). 0 Use the normal bit clock source. 1 Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.

Table continues on the next page...

Field	Description
27–26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip configuration details for the availability and chip-specific meaning of each option. 00 Bus Clock selected. 01 Master Clock (MCLK) 1 option selected. 10 Master Clock (MCLK) 2 option selected. 11 Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 Bit clock is generated externally in Slave mode. 1 Bit clock is generated internally in Master mode.
23–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

51.3.13 SAI Receive Configuration 3 Register (I2Sx_RCR3)

This register must not be altered when RCSR[RE] is set.

Address: Base address + 8Ch offset

I2Sx_RCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
7–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

51.3.16 SAI Receive Data Register (I2Sx_RDR*n*)

Reading this register introduces one additional peripheral clock wait state on each read.

Address: Base address + A0h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

I2Sx_RMR field descriptions

Field	Description
31–0 RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 0 Word N is enabled. 1 Word N is masked.

51.4 Functional description

51.4.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

51.4.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

51.4.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

51.4.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

51.4.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

51.4.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

51.4.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

51.4.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

51.4.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

51.4.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

51.4.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 32 × 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

51.4.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 51-112 for LSB First configurations and Figure 51-113 for MSB First configurations.

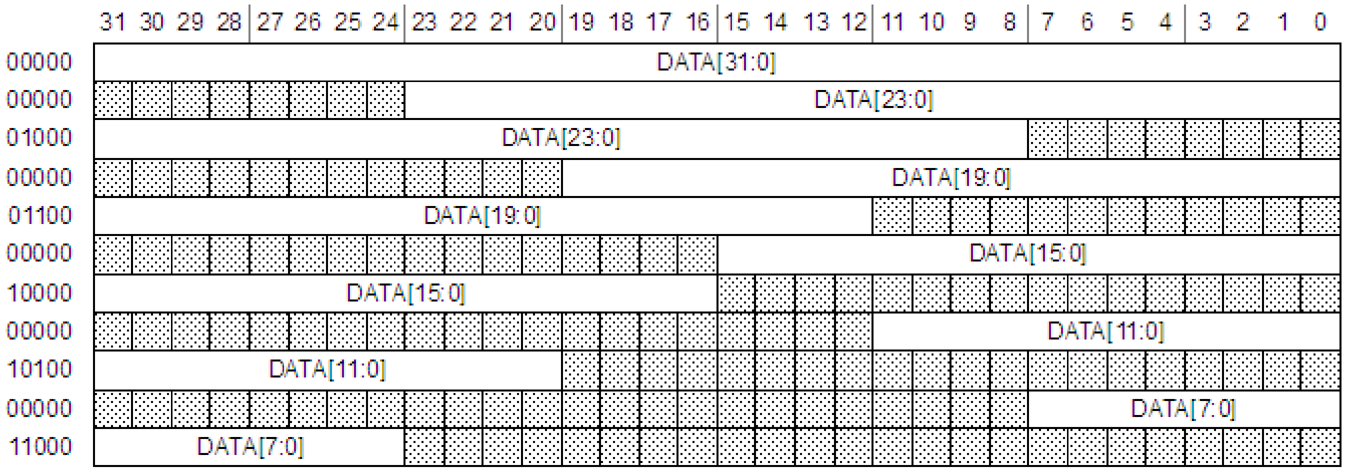

Figure 51-112. SAI first bit shifted, LSB first

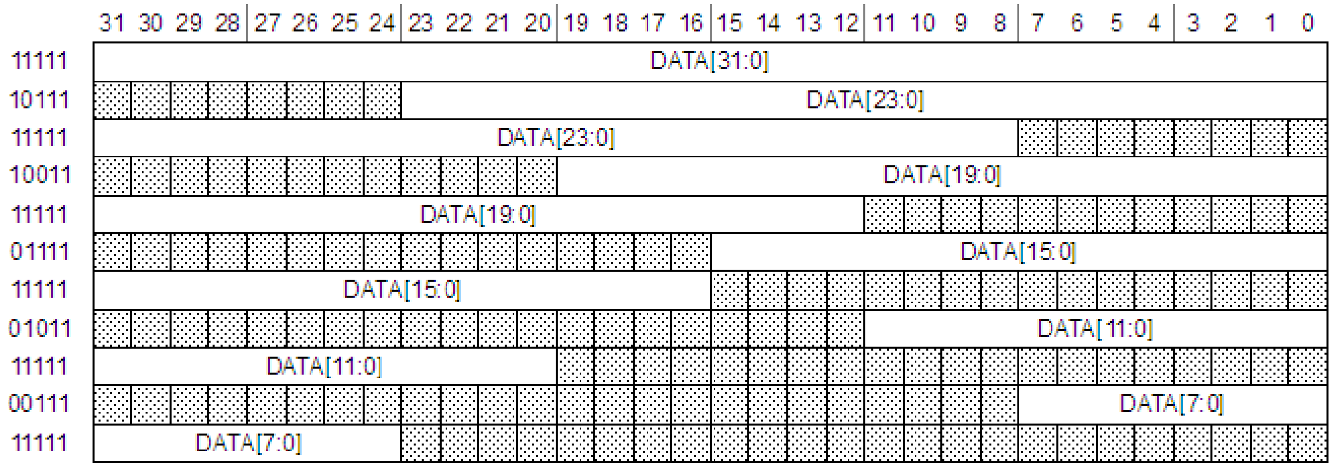

Figure 51-113. SAI first bit shifted, MSB first

51.4.5.2 FIFO pointers

When writing to a TDR, the WFP of the corresponding TFR increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the TDR and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data and 16-bit writes should only be used when transmitting up to 16-bit data.

Writes to a TDR are ignored if the corresponding bit of TCR3[TCE] is clear or if the FIFO is full. If the Transmit FIFO is empty, the TDR must be written at least three bit clocks before the start of the next unmasked word to avoid a FIFO underrun.

When reading an RDR, the RFP of the corresponding RFR increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data and 16-bit reads should only be used when receiving up to 16-bit data.

Reads from an RDR are ignored if the corresponding bit of RCR3[RCE] is clear or if the FIFO is empty. If the Receive FIFO is full, the RDR must be read at least three bit clocks before the end of an unmasked word to avoid a FIFO overrun.

51.4.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

51.4.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

51.4.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

51.4.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

51.4.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels repeat the last valid word read from the transmit FIFO until TCSR[FEF] is cleared and the next transmit frame starts. All enabled transmit FIFOs must be reset and initialized with new data before TCSR[FEF] is cleared.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

The FIFO error flag can generate only an interrupt.

51.4.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

51.4.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

Chapter 52
Enhanced Serial Audio Interface (ESAI)

52.1 Overview

The Enhanced Serial Audio Interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, Sony/Phillips Digital Interface (SPDIF) transceivers, and other DSPs.

The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. It is a superset of the 56300 Family ESSI peripheral and of the 56000 Family SAI peripheral.

All serial transfers in the module are synchronized to a clock. Additional synchronization signals are used to delineate the word frames. The normal mode of operation is used to transfer data at a periodic rate, one word per period. The network mode is similar in that it is also intended for periodic transfers; however, it supports up to 32 words (time slots) per period. This mode can be used to build time division multiplexed (TDM) networks. In contrast, the on-demand mode is intended for non-periodic transfers of data and to transfer data serially at high speed when the data becomes available.

The following figure shows the ESAI block diagram.

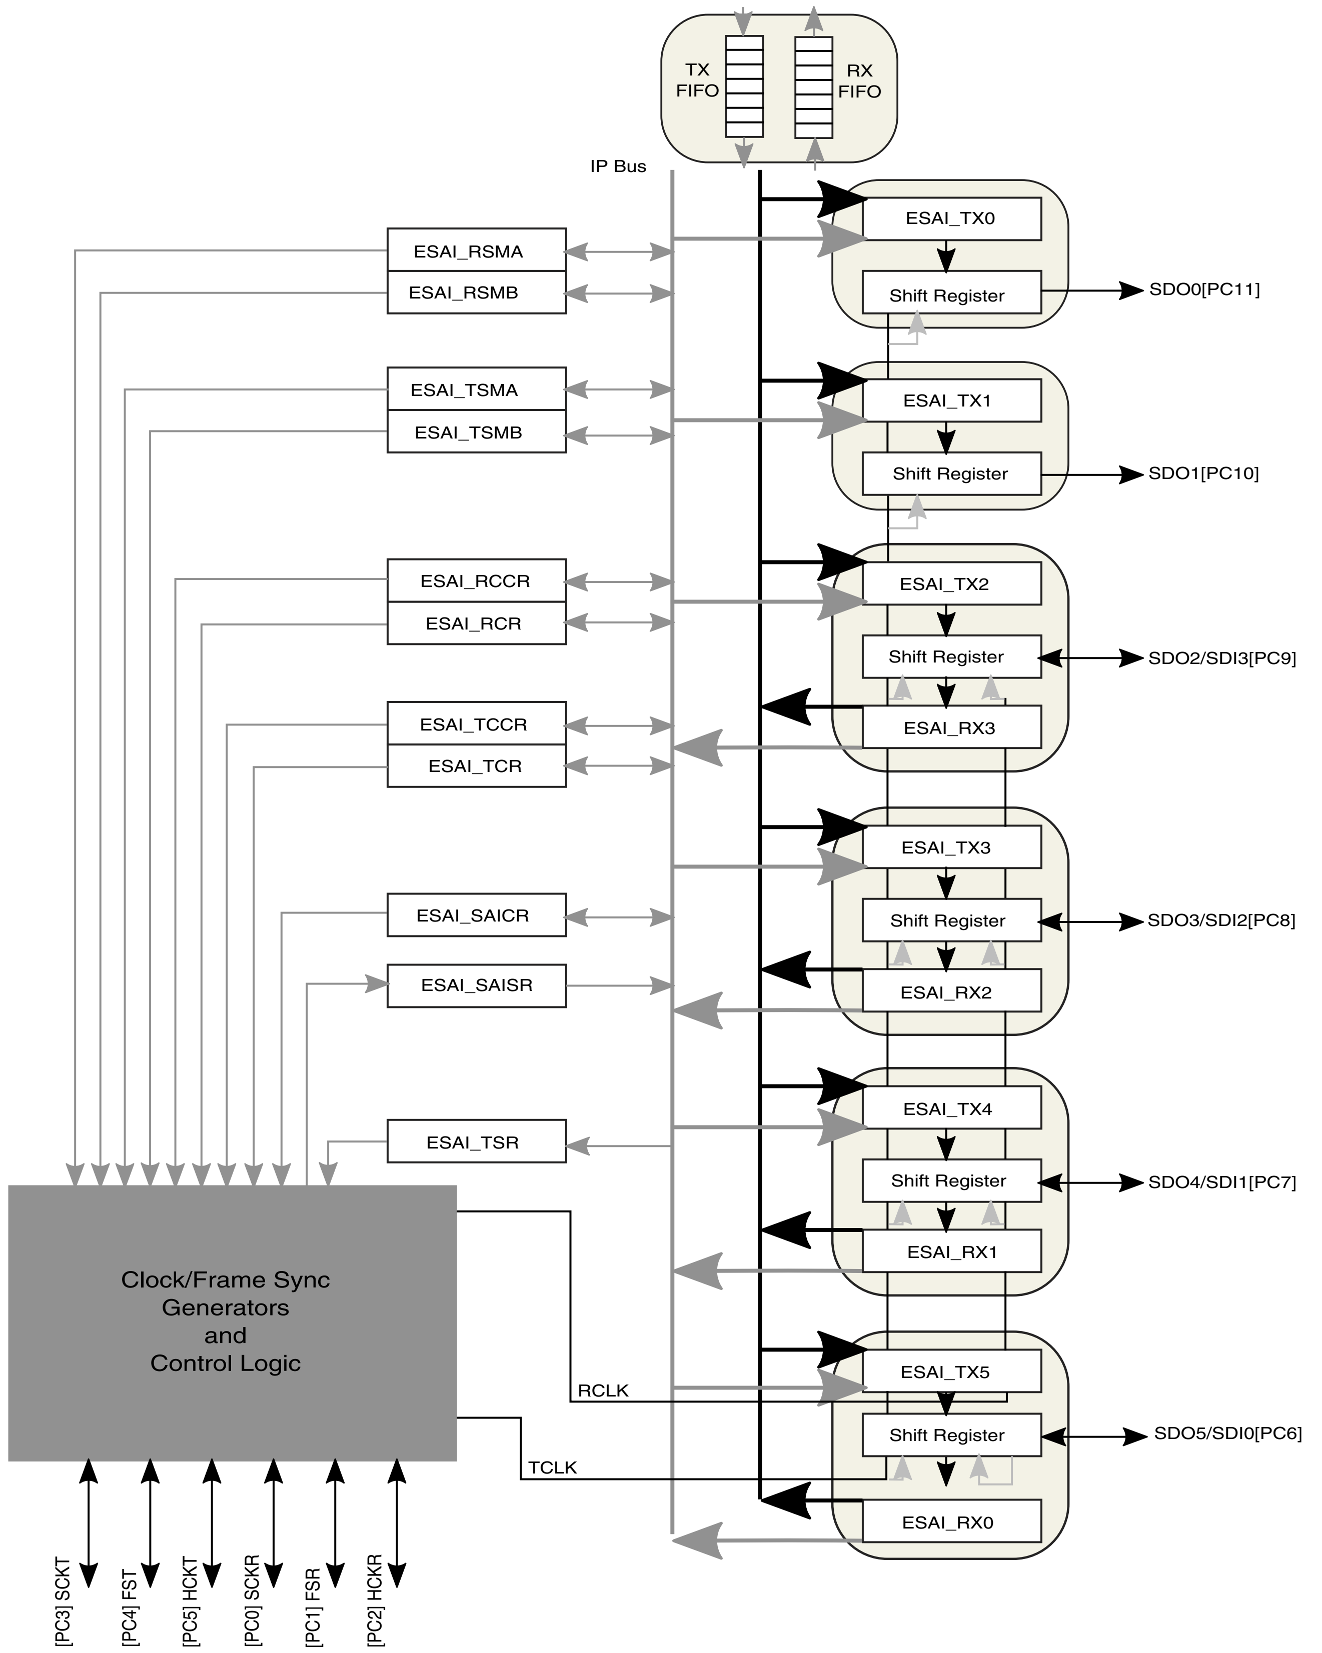

Figure 52-1. ESAI Block Diagram

52.1.1 Features

- Independent (asynchronous mode) or shared (synchronous mode) transmit and receive sections with separate or shared internal/external clocks and frame syncs, operating in Master or Slave mode.
- Up to six transmitters and four receivers with SDO2/SDI3, SDO3/SDI2, SDO4/SDI1 and SDO5/SDI0 pins shared by transmitters 2 to 5 and receivers 0 to 3. SDO0 and SDO1 pins are used by transmitters 0 and 1 only.
- Programmable data interface modes such as I2S, LSB aligned, MSB aligned
- Programmable word length (8, 12, 16, 20 or 24bits)
- Flexible selection between system clock or external oscillator as input clock source, programmable internal clock divider and frame sync generation
- AC97 support
- Time Slot Mask Registers for reduced ARM platform overhead (for both Transmit and Receive)
- 128-word Transmit FIFO shared by six transmitters
- 128-word Receive FIFO shared by four receivers

52.1.2 Modes of Operation

ESAI has three basic operating modes and many data/operation formats.

ESAI operating mode are selected by the ESAI control registers (ESAI_TCCR, ESAI_TCR, ESAI_RCCR, ESAI_RCR, and ESAI_SAICR). The main operating modes are described in the following section.

52.1.2.1 Normal/Network/On-Demand Mode Selection

Selecting between the normal mode and network mode is accomplished by clearing or setting the TMOD0-TMOD1 bits in the ESAI_TCR register for the transmitter section, as well as in the RMOD0-RMOD1 bits in the ESAI_RCR register for the receiver section.

For normal mode, the ESAI functions with one data word of I/O per frame (per enabled transmitter or receiver). The normal mode is typically used to transfer data to or from a single device.

For the network mode, 2 to 32 time slots per frame may be selected. During each frame, 0 to 32 data words of I/O may be received or transmitted. In either case, the transfers are periodic. The frame sync signal indicates the first time slot in the frame. Network mode is typically used in time division multiplexed (TDM) networks of codecs, DSPs with multiple words per frame, or multi-channel devices.

Selecting the network mode and setting the frame rate divider to zero (DC=00000) selects the on-demand mode. This special case does not generate a periodic frame sync. A frame sync pulse is generated only when data is available to transmit. The on-demand mode requires that the transmit frame sync be internal (output) and the receive frame sync be external (input). Therefore, for simplex operation, the synchronous mode could be used; however, for full-duplex operation, the asynchronous mode must be used. Data transmission that is data driven is enabled by writing data into each TX. Although the ESAI is double buffered, only one word can be written to each TX, even if the transmit shift register is empty. The receive and transmit interrupts function as usual using TDE and RDF; however, transmit underruns are impossible for on-demand transmission and are disabled.

52.1.2.2 Synchronous/Asynchronous Operating Modes

The transmit and receive sections of the ESAI may be synchronous or asynchronous, that is, the transmitter and receiver sections may use common clock and synchronization signals (synchronous operating mode), or they may have their own separate clock and sync signals (asynchronous operating mode).

The SYN bit in the ESAI_SAICR register selects synchronous or asynchronous operation. Because the ESAI is designed to operate either synchronously or asynchronously, separate receive and transmit interrupts are provided.

When SYN is cleared, the ESAI transmitter and receiver clocks and frame sync sources are independent. If SYN is set, the ESAI transmitter and receiver clocks and frame sync come from the transmitter section (either external or internal sources).

Data clock and frame sync signals can be generated internally by the ARM Core or may be obtained from external sources. If internally generated, the ESAI clock generator is used to derive high frequency clock, bit clock and frame sync signals from the ARM Core internal system clock.

52.1.2.3 Frame Sync Selection

The frame sync can be either a bit-long or word-long signal.

The transmitter frame format is defined by the TFSL bit in the ESAI_TCR register. The receiver frame format is defined by the RFSL bit in the ESAI_RCR register.

1. In the word-long frame sync format, the frame sync signal is asserted during the entire word data transfer period. This frame sync length is compatible with codecs, SPI serial peripherals, serial A/D and D/A converters, shift registers and telecommunication PCM serial I/O.
2. In the bit-long frame sync format, the frame sync signal is asserted for one bit clock immediately before the data transfer period. This frame sync length is compatible with Intel and National components, codecs and telecommunication PCM serial I/O.

The relative timing of the word length frame sync as referred to the data word is specified by the TFSR bit in the ESAI_TCR register for the transmitter section and by the RFSR bit in the ESAI_RCR register for the receive section. The word length frame sync may be generated (or expected) with the first bit of the data word, or with the last bit of the previous word. TFSR and RFSR are ignored when a bit length frame sync is selected.

Polarity of the frame sync signal may be defined as positive (asserted high) or negative (asserted low). The TFSP bit in the ESAI_TCCR register specifies the polarity of the frame sync for the transmitter section. The RFSP bit in the ESAI_RCCR register specifies the polarity of the frame sync for the receiver section.

The ESAI receiver looks for a receive frame sync leading edge (trailing edge if RFSP is set) only when the previous frame is completed. If the frame sync goes high before the frame is completed (or before the last bit of the frame is received in the case of a bit frame sync or a word length frame sync with RFSR set), the current frame sync is not recognized, and the receiver is internally disabled until the next frame sync. Frames do not have to be adjacent, that is, a new frame sync does not have to immediately follow the previous frame. Gaps of arbitrary periods can occur between frames. Enabled transmitters are tri-stated during these gaps.

When operating in the synchronous mode (SYN=1), all clocks including the frame sync are generated by the transmitter section.

52.1.2.4 Shift Direction Selection

Some data formats, such as those used by codecs, specify MSB first while other data formats, such as the AES-EBU digital audio interface, specify LSB first.

The MSB/LSB first selection is made by programming RSHFD bit in the ESAI_RCR register for the receiver section and by programming the TSHFD bit in the ESAI_TCR register for the transmitter section.

52.2 External Signals

Three to twelve pins are required for operation, depending on the operating mode selected and the number of transmitters and receivers enabled.

The SDO0 and SDO1 pins are used by transmitters 0 and 1 only. The SDO2/SDI3, SDO3/SDI2, SDO4/SDI1 and SDO5/SDI0 pins are shared by transmitters 2 to 5 with receivers 0 to 3. The actual mode of operation is selected under software control. All transmitters operate fully synchronized under control of the same transmitter clock signals. All receivers operate fully synchronized under control of the same receiver clock signals.

Table 52-1. ESAI External Signals

Signal	Description	Pad	Mode	Direction
ESAI_RX_CLK	RX serial bit clock for the ESAI interface. The direction can be programmed.	ENET_MDIO	ALT2	IO
		GPIO_1	ALT0	
ESAI_RX_FS	RX frame sync signal for the ESAI interface.	ENET_REF_CLK	ALT2	IO
		GPIO_9	ALT0	
ESAI_RX_HF_CLK	RX high frequency clock for the ESAI interface.	ENET_RX_ER	ALT2	IO
		GPIO_3	ALT0	
ESAI_TX0	Used for transmitting data from the ESAI_TX0 serial transmit shift register.	GPIO_17	ALT0	IO
		NANDF_CS2	ALT2	
ESAI_TX1	Used for transmitting data from the ESAI_TX1 serial transmit shift register.	GPIO_18	ALT0	IO
		NANDF_CS3	ALT2	
ESAI_TX2_RX3	Used as TX2 for transmitting data from the ESAI_TX2 serial transmit shift register when programmed as a transmitter pin Used as the RX3 signal for receiving serial data to the ESAI_RX3 serial receive shift register when programmed as a receiver pin	ENET_TXD1	ALT2	IO
		GPIO_5	ALT0	
ESAI_TX3_RX2	Used as TX3 for transmitting data from the ESAI_TX2 serial transmit shift register when programmed as a transmitter pin Used as the RX2 signal for receiving serial data to the ESAI_RX3 serial receive shift register when programmed as a receiver pin	ENET_TX_EN	ALT2	IO
		GPIO_16	ALT0	

Table continues on the next page...

Table 52-1. ESAI External Signals (continued)

Signal	Description	Pad	Mode	Direction
ESAI_TX4_RX1	Used as TX4 for transmitting data from the ESAI_TX2 serial transmit shift register when programmed as a transmitter pin Used as the RX1 signal for receiving serial data to the ESAI_RX3 serial receive shift register when programmed as a receiver pin	ENET_TXD0	ALT2	IO
		GPIO_7	ALT0	
ESAI_TX5_RX0	Used as TX5 for transmitting data from the ESAI_TX2 serial transmit shift register when programmed as a transmitter pin Used as the RX0 signal for receiving serial data to the ESAI_RX3 serial receive shift register when programmed as a receiver pin	ENET_MDC	ALT2	IO
		GPIO_8	ALT0	
ESAI_TX_CLK	TX serial bit clock for the ESAI interface. The direction can be programmed.	ENET_CRS_DV	ALT2	IO
		GPIO_6	ALT0	
ESAI_TX_FS	Frame sync for both the transmitters and receivers in the synchronous mode (SYN=1) and for the transmitters only in asynchronous mode	ENET_RXD1	ALT2	IO
		GPIO_2	ALT0	
ESAI_TX_HF_CLK	TX high frequency clock for the ESAI interface.	ENET_RXD0	ALT2	IO
		GPIO_4	ALT0	

52.2.1 Serial Transmit 0 Data Pin

SDO0 is used for transmitting data from the ESAI_TX0 serial transmit shift register.

SDO0 is an output when data is being transmitted from the ESAI_TX0 shift register. In the on-demand mode with an internally generated bit clock, the SDO0 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO0 may be programmed as a disconnected pin (PC11) when the ESAI SDO0 function is not being used. (See Table 52-47.)

52.2.2 Serial Transmit 1 Data Pin

SDO1 is used for transmitting data from the ESAI_TX1 serial transmit shift register.

SDO1 is an output when data is being transmitted from the ESAI_TX1 shift register. In the on-demand mode with an internally generated bit clock, the SDO1 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO1 may be programmed as a disconnected pin (PC10) when the ESAI SDO1 function is not being used. (See Table 52-47.)

52.2.3 Serial Transmit 2/Receive 3 Data Pin

SDO2/SDI3 is used as the SDO2 for transmitting data from the ESAI_TX2 serial transmit shift register when programmed as a transmitter pin, or as the SDI3 signal for receiving serial data to the ESAI_RX3 serial receive shift register when programmed as a receiver pin.

SDO2/SDI3 is an input when data is being received by the ESAI_RX3 shift register. SDO2/SDI3 is an output when data is being transmitted from the ESAI_TX2 shift register. In the on-demand mode with an internally generated bit clock, the SDO2/SDI3 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO2/SDI3 may be programmed as a disconnected pin (PC9) when the ESAI SDO2 and SDI3 functions are not being used. (See Table 52-47.)

52.2.4 Serial Transmit 3/Receive 2 Data Pin

SDO3/SDI2 is used as the SDO3 signal for transmitting data from the ESAI_TX3 serial transmit shift register when programmed as a transmitter pin, or as the SDI2 signal for receiving serial data to the ESAI_RX2 serial receive shift register when programmed as a receiver pin.

SDO3/SDI2 is an input when data is being received by the ESAI_RX2 shift register. SDO3/SDI2 is an output when data is being transmitted from the ESAI_TX3 shift register. In the on-demand mode with an internally generated bit clock, the SDO3/SDI2

pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO3/SDI2 may be programmed as a disconnected pin (PC8) when the ESAI SDO3 and SDI2 functions are not being used. (See Table 52-47.)

52.2.5 Serial Transmit 4/Receive 1 Data Pin

SDO4/SDI1 is used as the SDO4 signal for transmitting data from the ESAI_TX4 serial transmit shift register when programmed as transmitter pin, or as the SDI1 signal for receiving serial data to the RX1 serial receive shift register when programmed as a receiver pin.

SDO4/SDI1 is an input when data is being received by the ESAI_RX1 shift register. SDO4/SDI1 is an output when data is being transmitted from the ESAI_TX4 shift register. In the on-demand mode with an internally generated bit clock, the SDO4/SDI1 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO4/SDI1 may be programmed as a disconnected pin (PC7) when the ESAI SDO4 and SDI1 functions are not being used. (See Table 52-47.)

52.2.6 Serial Transmit 5/Receive 0 Data Pin

SDO5/SDI0 is used as the SDO5 signal for transmitting data from the ESAI_TX5 serial transmit shift register when programmed as transmitter pin, or as the SDI0 signal for receiving serial data to the ESAI_RX0 serial shift register when programmed as a receiver pin.

SDO5/SDI0 is an input when data is being received by the ESAI_RX0 shift register. SDO5/SDI0 is an output when data is being transmitted from the ESAI_TX5 shift register. In the on-demand mode with an internally generated bit clock, the SDO5/SDI0 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO5/SDI0 may be programmed as a disconnected pin (PC6) when the ESAI SDO5 and SDI0 functions are not being used. (See Table 52-47.)

52.2.7 Receiver Serial Clock

SCKR is a bidirectional pin providing the receivers serial bit clock for the ESAI interface.

The direction of this pin is determined by the RCKD bit in the ESAI_RCCR register.The SCKR operates as a clock input or output used by all the enabled receivers in the asynchronous mode (SYN=0), or as serial flag 0 pin in the synchronous mode (SYN=1).

When this pin is configured as serial flag pin, its direction is determined by the RCKD bit in the ESAI_RCCR register. When configured as the output flag OF0, this pin reflects the value of the OF0 bit in the ESAI_SAICR register, and the data in the OF0 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When this pin is configured as the input flag IF0, the data value at the pin is stored in the IF0 bit in the ESAI_SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

SCKR may be programmed as a disconnected pin (PC0) when the ESAI SCKR function is not being used. (See Table 52-47.)

NOTE

Although the external ESAI serial clocks can be independent of and asynchronous to the internal 133 MHz ESAI system clock, the external ESAI serial clock frequency cannot exceed 133MHz/4 = 33.25 MHz and each external ESAI serial clock phase must exceed the minimum of 2 x 1/133MHz = 15.04ns.

For SCKR pin mode definitions, see Table 52-38.

The table below provides a list of asynchronous-mode receiver clock sources. For more information about EXTAL/ESAI clocking control bits (ERI, ERO), refer to ESAI Control Register (ESAI_ECR).

Table 52-2. Receiver Clock Sources (Asynchronous Mode Only)

RHCKD	RFSD	RCKD	ERI	ERO	Receiver Bit Clock Source	OUTPUTS		
0	0	0	N/A	N/A	SCKR	-	-	-

1	1	1	1	1	EXTAL	HCKR	FSR	SCKR
EXTAL is the on-chip clock source other than ESAI system 133MHz clock, and it is from esai_clk_root in CCM								

52.2.8 Transmitter Serial Clock

SCKT is a bidirectional pin providing the transmitters serial bit clock for the ESAI interface.

The direction of this pin is determined by the TCKD bit in the ESAI_TCCR register. The SCKT is a clock input or output used by all the enabled transmitters in the asynchronous mode (SYN=0) or by all the enabled transmitters and receivers in the synchronous mode (SYN=1).

The following table provides a list of asynchronous-mode transmitter clock sources.

Table 52-3. Transmitter Clock Sources (Asynchronous Mode Only)

THCKD	TFSD	TCKD	ETI	ETO	Transmitter Bit Clock Source	OUTPUTS		
0	0	0	N/A	N/A	SCKT	-	-	-
0	0	1	N/A	N/A	HCKT	-	-	SCKT
0	1	0	N/A	N/A	SCKT	-	FST	-
0	1	1	N/A	N/A	HCKT	-	FST	SCKT

Table continues on the next page...

Table 52-3. Transmitter Clock Sources (Asynchronous Mode Only) (continued)

1	1	0	1	1	SCKR	HCKT	FST	-
1	1	1	0	0	Fsys	HCKT	FST	SCKT
1	1	1	0	1	Fsys	HCKT	FST	SCKT
1	1	1	1	0	EXTAL	HCKT	FST	SCKT
1	1	1	1	1	EXTAL	HCKT	FST	SCKT
EXTAL is the on-chip clock sources other than ESAI system 133MHz clock, and it is from esai_clk_root in CCM								

SCKT may be programmed as a disconnected pin (PC3) when the ESAI SCKT function is not being used. (See Table 52-47.)

For more information about EXTAL/ESAI clocking control bits (ETI, ETO), see ESAI Control Register (ESAI_ECR).

NOTE

Although the external ESAI serial clocks can be independent of and asynchronous to the internal 133 MHz ESAI system clock, the external ESAI serial clock frequency cannot exceed 133MHz/4 = 33.25 MHz and each external ESAI serial clock phase must exceed the minimum of 2 x 1/133MHz = 15.04ns.

52.2.9 Frame Sync for Receiver

FSR is a bidirectional pin providing the receivers frame sync signal for the ESAI interface. The direction of this pin is determined by the RFSD bit in ESAI_RCR register.

In the asynchronous mode (SYN=0), the FSR pin operates as the frame sync input or output used by all the enabled receivers. In the synchronous mode (SYN=1), it operates as either the serial flag 1 pin (TEBE=0), or as the transmitter external buffer enable control (TEBE=1, RFSD=1). For FSR pin mode definitions, see Table 52-39; for receiver clock signals, see Table 52-2.

When this pin is configured as serial flag pin, its direction is determined by the RFSD bit in the ESAI_RCCR register. When configured as the output flag OF1, this pin reflects the value of the OF1 bit in the ESAI_SAICR register, and the data in the OF1 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When configured as the input flag IF1, the data value at the pin is stored in the IF1 bit in the ESAI_SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

FSR may be programmed as a disconnected pin (PC1) when the ESAI FSR function is not being used. (See Table 52-47.)

52.2.10 Frame Sync for Transmitter

FST is a bidirectional pin providing the frame sync for both the transmitters and receivers in the synchronous mode (SYN=1) and for the transmitters only in asynchronous mode

(SYN=0) (see Table 52-3). The direction of this pin is determined by the TFSD bit in the ESAI_TCR register. When configured as an output, this pin is the internally generated frame sync signal. When configured as an input, this pin receives an external frame sync signal for the transmitters (and the receivers in synchronous mode).

FST may be programmed as a disconnected pin (PC4) when the ESAI FST function is not being used. (See Table 52-47.)

52.2.11 High Frequency Clock for Transmitter

HCKT is a bidirectional pin providing the transmitters high frequency clock for the ESAI interface.

The direction of this pin is determined by the THCKD bit in the ESAI_TCCR register. In the asynchronous mode (SYN=0), the HCKT pin operates as the high frequency clock input or output used by all enabled transmitters. In the synchronous mode (SYN=1), it operates as the high frequency clock input or output used by all enabled transmitters and receivers. When programmed as input this pin is used as an alternative high frequency

clock source to the ESAI transmitter rather than the ARM Core main clock. When programmed as output it can serve as a high frequency sample clock (to external DACs for example) or as an additional system clock (see Table 52-3).

HCKT may be programmed as a disconnected pin (PC5) when the ESAI HCKT function is not being used. (See Table 52-47.)

52.2.12 High Frequency Clock for Receiver

HCKR is a bidirectional pin providing the receivers high frequency clock for the ESAI interface.

The direction of this pin is determined by the RHCKD bit in the ESAI_RCCR register. In the asynchronous mode (SYN=0), the HCKR pin operates as the high frequency clock input or output used by all the enabled receivers. In the synchronous mode (SYN=1), it operates as the serial flag 2 pin. For HCKR pin mode definitions, see Table 52-40; for receiver clock signals, see Table 52-2.

When this pin is configured as serial flag pin, its direction is determined by the RHCKD bit in the ESAI_RCCR register. When configured as the output flag OF2, this pin reflects the value of the OF2 bit in the ESAI_SAICR register, and the data in the OF2 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When configured as the input flag IF2, the data value at the pin is stored in the IF2 bit in the ESAI_SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

HCKR may be programmed as a disconnected pin (PC2) when the ESAI HCKR function is not being used. (See Table 52-47.)

52.2.13 Serial I/O Flags

Three ESAI pins (FSR, SCKR and HCKR) are available as serial I/O flags when the ESAI is operating in the synchronous mode (SYN=1).

Their operation is controlled by RCKD, RFSD, TEBE bits in the ESAI_RCR, ESAI_RCCR and ESAI_SAICR registers.The output data bits (OF2, OF1 and OF0) and the input data bits (IF2, IF1 and IF0) are double buffered to/from the HCKR, FSR and SCKR pins. Double buffering the flags keeps them in sync with the TX and RX data lines.

Each flag can be separately programmed. Flag 0 (SCKR pin) direction is selected by RCKD, RCKD=1 for output and RCKD=0 for input. Flag 1 (FSR pin) is enabled when the pin is not configured as external transmitter buffer enable (TEBE=0) and its direction is selected by RFSD, RFSD=1 for output and RFSD=0 for input. Flag 2 (HCKR pin) direction is selected by RHCKD, RHCKD=1 for output and RHCKD=0 for input.

When programmed as input flags, the SCKR, FSR and HCKR logic values, respectively, are latched at the same time as the first bit of the receive data word is sampled. Because the input was latched, the signal on the input flag pin (SCKR, FSR or HCKR) can change without affecting the input flag until the first bit of the next receive data word. When the received data words are transferred to the receive data registers, the input flag latched values are then transferred to the IF0, IF1 and IF2 bits in the SAISR register, where they may be read by software.

When programmed as output flags, the SCKR, FSR and HCKR logic values are driven by the contents of the OF0, OF1 and OF2 bits in the ESAI_SAICR register respectively, and they are driven when the transmit data registers are transferred to the transmit shift registers. The value on SCKR, FSR and HCKR is stable from the time the first bit of the transmit data word is transmitted until the first bit of the next transmit data word is transmitted. Software may change the OF0-OF2 values thus controlling the SCKR, FSR and HCKR pin values for each transmitted word. The normal sequence for setting output flags when transmitting data is as follows: wait for TDE (transmitter empty) to be set; first write the flags, and then write the transmit data to the transmit registers. OF0, OF1, and OF2 are double buffered so that the flag states appear on the pins when the transmit data is transferred to the transmit shift register, that is, the flags are synchronous with the data.

52.3 Functional Description

This section provides a complete functional description of the block.

52.3.1 ESAI After Reset

Hardware or software reset clears the port control register bits and the port direction control register bits, which configure all ESAI I/O pins as disconnected and both ESAI FIFOs are also in reset state.

The ESAI is in personal reset state while all ESAI pins are programmed as disconnected, and it is active only if at least one of the ESAI I/O pins is programmed as an ESAI pin.

52.3.2 ESAI Interrupt Requests

The ESAI can generate eight different interrupt requests

(ordered from the highest to the lowest priority):

1. **ESAI Receive Data with Exception Status**

   Occurs when the receive exception interrupt is enabled (REIE=1 in the RCR register), at least one of the enabled receive data registers is full (RDF=1) and a receiver overrun error has occurred (ROE=1 in the SAISR register). ROE is cleared by first reading the SAISR and then reading all the enabled receive data registers.

2. **ESAI Receive Even Data**

   Occurs when the receive even slot data interrupt is enabled (REDIE=1), at least one of the enabled receive data registers is full (RDF=1), the data is from an even slot (REDF=1) and no exception has occurred (ROE=0 or REIE=0).

   Reading all enabled receiver data registers clears RDF and REDF.

3. **ESAI Receive Data**

   Occurs when the receive interrupt is enabled (RIE=1), at least one of the enabled receive data registers is full (RDF=1), no exception has occurred (ROE=0 or REIE=0) and no even slot interrupt has occurred (REDF=0 or REDIE=0). Reading all enabled receiver data registers clears RDF.

4. **ESAI Receive Last Slot Interrupt**

   Occurs, if enabled (RLIE=1), after the last slot of the frame ended (in network mode only) regardless of the receive mask register setting. The receive last slot interrupt may be used for resetting the receive mask slot register, reconfiguring the DMA channels and reassigning data memory pointers. Using the receive last slot interrupt guarantees that the previous frame was serviced with the previous setting and the new frame is serviced with the new setting without synchronization problems. Note that the maximum receive last slot interrupt service time should not exceed N-1 ESAI bits service time (where N is the number of bits in a slot).

5. **ESAI Transmit Data with Exception Status**

   Occurs when the transmit exception interrupt is enabled (TEIE=1), at least one transmit data register of the enabled transmitters is empty (TDE=1) and a transmitter underrun error has occurred (TUE=1). TUE is cleared by first reading the SAISR and then writing to all the enabled transmit data registers, or to the TSR register.

6. **ESAI Transmit Last Slot Interrupt**

   Occurs, if enabled (TLIE=1), at the start of the last slot of the frame in network mode regardless of the transmit mask register setting. The transmit last slot interrupt may be used for resetting the transmit mask slot register, reconfiguring the DMA channels and reassigning data memory pointers. Using the transmit last slot interrupt guarantees that the previous frame was serviced with the previous setting and the new frame is serviced with the new setting without synchronization problems. Note that the maximum transmit last slot interrupt service time should not exceed N-1 ESAI bits service time (where N is the number of bits in a slot).

7. **ESAI Transmit Even Data**

   Occurs when the transmit even slot data interrupt is enabled (TEDIE=1), at least one of the enabled transmit data registers is empty (TDE=1), the slot is an even slot (TEDE=1) and no exception has occurred (TUE=0 or TEIE=0). Writing to all the TX registers of the enabled transmitters or to TSR clears this interrupt request.

8. **ESAI Transmit Data**

   Occurs when the transmit interrupt is enabled (TIE=1), at least one of the enabled transmit data registers is empty (TDE=1), no exception has occurred (TUE=0 or TEIE=0) and no even slot interrupt has occurred (TEDE=0 or TEDIE=0). Writing to all the TX registers of the enabled transmitters, or to the TSR clears this interrupt request.

52.3.3 ESAI DMA Requests from the FIFOs

The ESAI can generate two different DMA requests:

1. ESAI Transmit FIFO Empty - Asserts when the number of empty slots in the ESAI transmit FIFO exceeds the threshold programmed in the ESAI Transmit FIFO Configuration Register (TFCR). Automatically negates when the number of empty slots is less than the threshold programmed in the ESAI Transmit FIFO Configuration Register.
2. ESAI Receive FIFO Full - Asserts when the number of data words in the ESAI receive FIFO exceeds the threshold programmed in the ESAI Receive FIFO Configuration Register (RFCR). Automatically negates when the number of words is less than the threshold programmed in the ESAI Receive FIFO Configuration Register.

52.3.4 ESAI Transmit and Receive Shift Registers

52.3.4.1 ESAI Transmit Shift Registers

The transmit shift registers contain the data being transmitted

(Figure 52-2 and Figure 52-3).

Data is shifted out to the serial transmit data pins by the selected (internal/external) bit clock when the associated frame sync I/O is asserted.

The number of bits shifted out before the shift registers are considered empty and may be written to again can be 8, 12, 16, 20, 24 or 32 bits (determined by the slot length control bits in the TCR register). Data is shifted out of these registers MSB first if TSHFD=0 and LSB first if TSHFD=1.

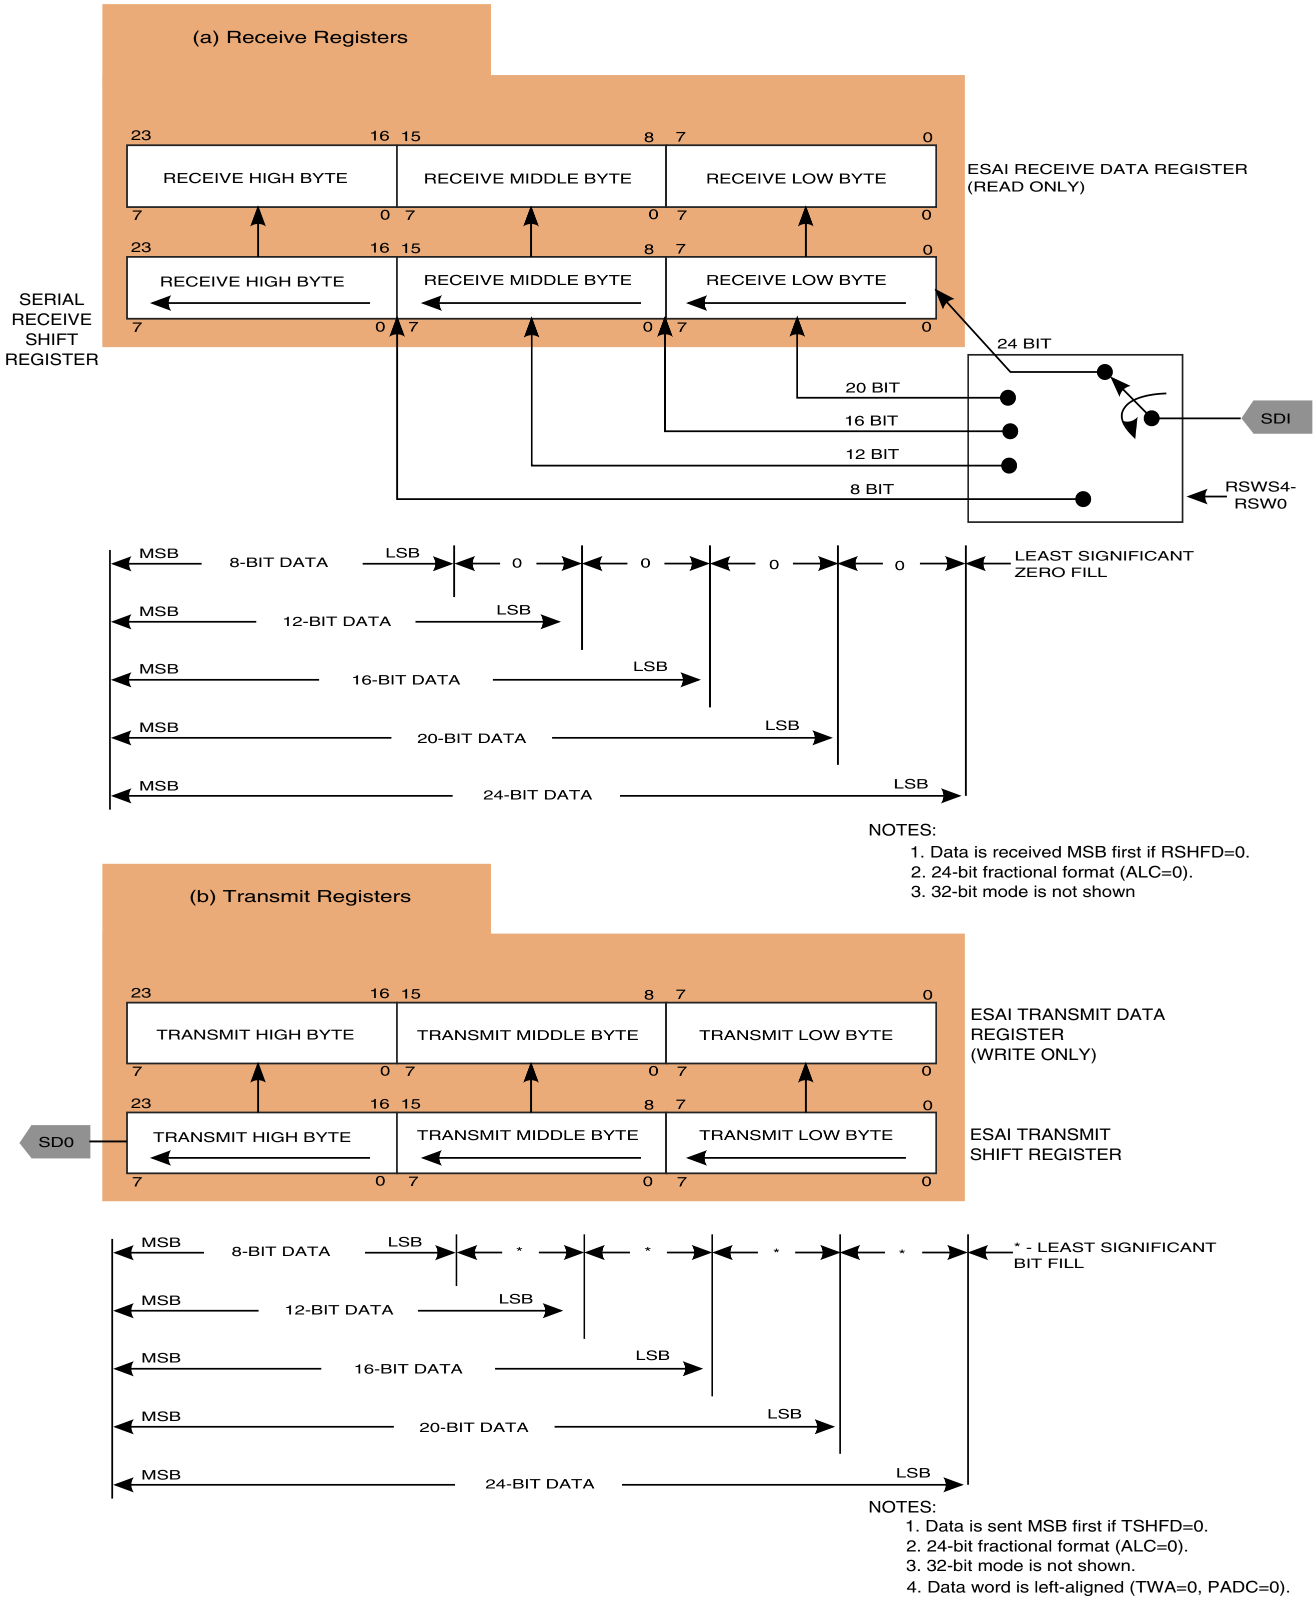

Figure 52-2. ESAI Data Path Programming Model ([R/T]SHFD=0)

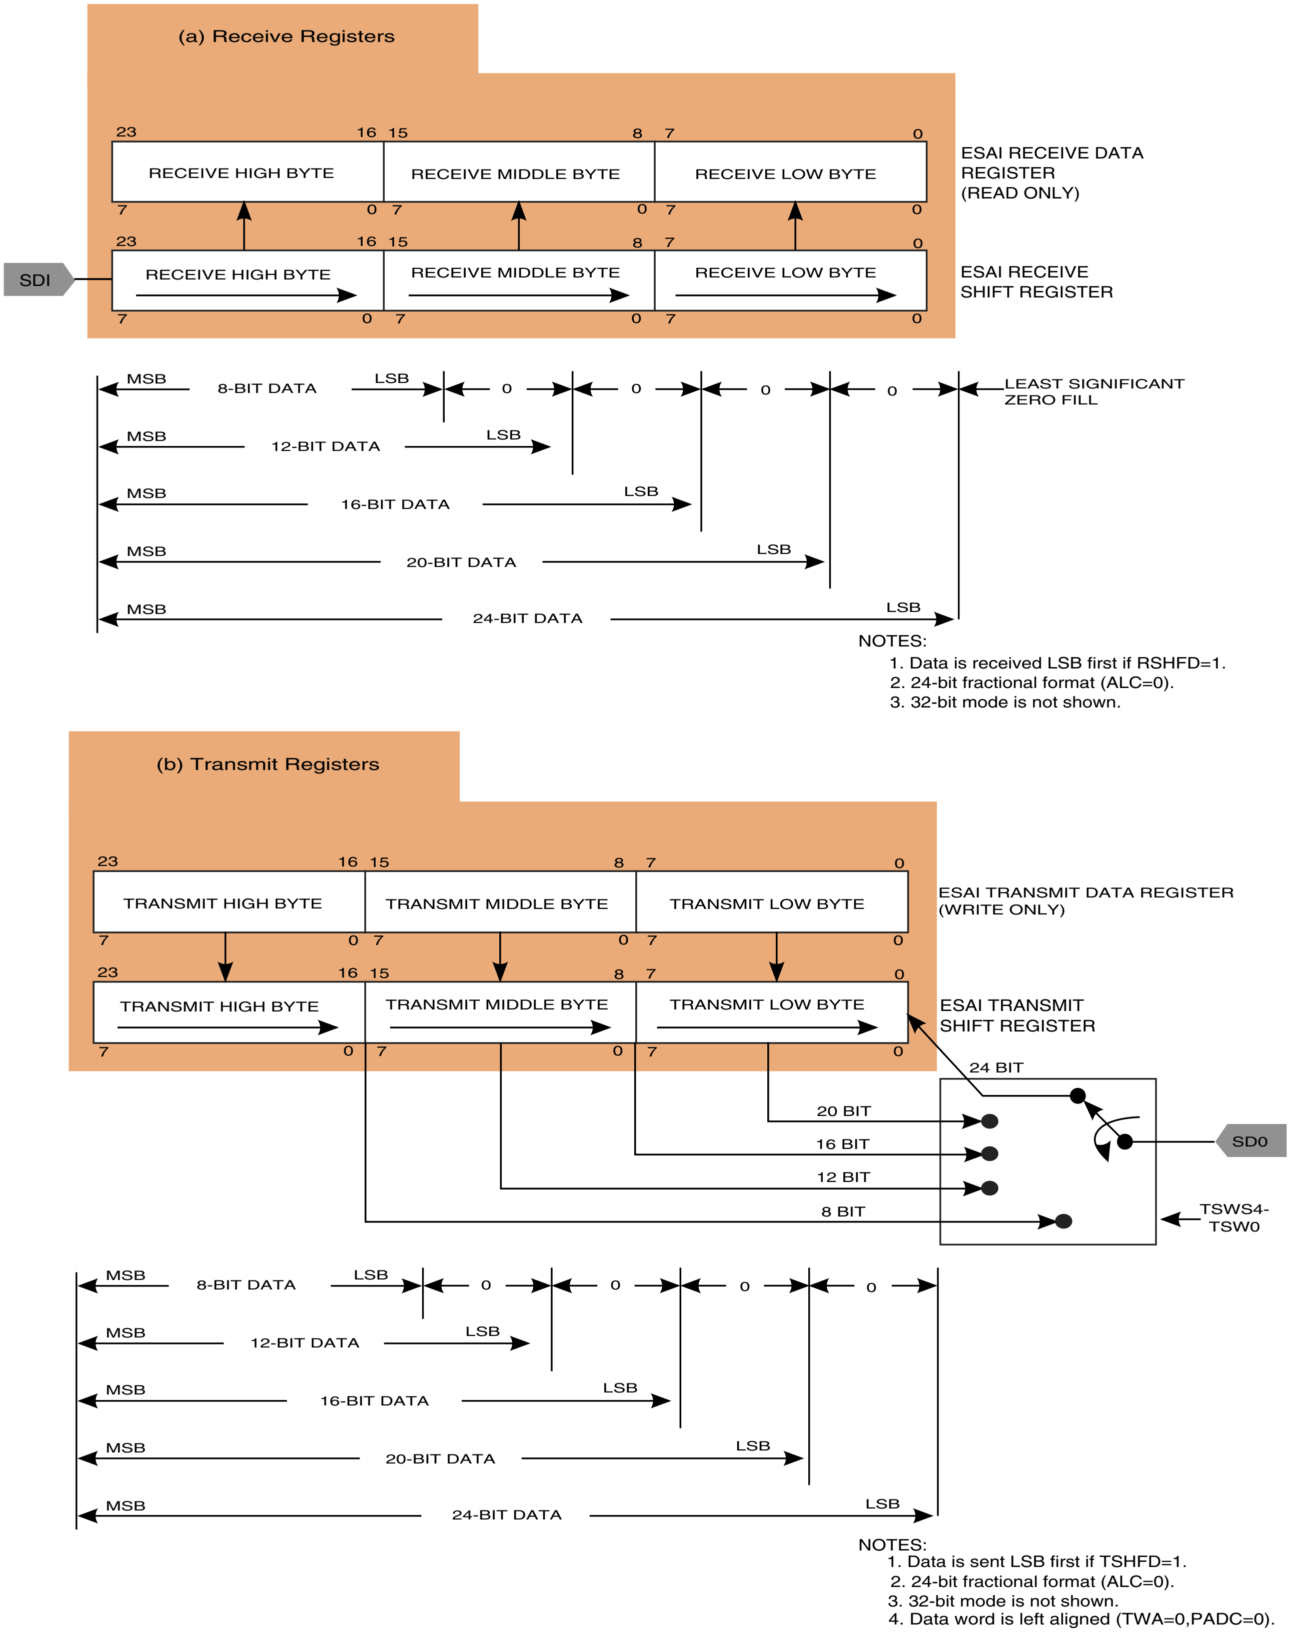

Figure 52-3. ESAI Data Path Programming Model ([R/T]SHFD=1)

52.3.4.2 ESAI Receive Shift Registers

The receive shift registers (Figure 52-2 and Figure 52-3) receive the incoming data from the serial receive data pins. Data is shifted in by the selected (internal/external) bit clock when the associated frame sync I/O is asserted. Data is assumed to be received MSB first if RSHFD=0 and LSB first if RSHFD=1. Data is transferred to the ESAI receive data registers after 8, 12, 16, 20, 24, or 32 serial clock cycles were counted, depending on the slot length control bits in the ESAI_RCR register.

52.4 Initialization Information

52.4.1 ESAI Initialization

The correct way to initialize the ESAI is as follows:

1. Enable the ESAI logic clock by asserting bit 0 of ESAI Control Register (ESAI_ECR[0]).
2. Hardware, software, ESAI individual reset. Note that asserting bit 1 of ESAI Control Register only reset the ESAI core logic, including configuration registers, but not the ESAI FIFOs.
3. Reset ESAI FIFOs by asserting bit 1 of ESAI_TFCR and ESAI_RFCR.
4. Program ESAI control and time slot registers.(The transmit/receive enable bits of TCR/RCR should not be set.)
5. Program ESAI FIFOs via TFCR and RFCR. (Enable Transmit/Receive FIFO, enable transmitters/receivers, transmit initialization and set Transmit FIFO/Receive FIFO watermark.)
6. Write initial words to ESAI Transmit Data Register (ESAI_ETDR), at least one word per enabled transmitter slot but as many as desired. For example 4 channels with 2 slot-per-channel are enabled, then 8 words need to be written into ESAI_ETDR
7. Remove ESAI personal reset by configuring ESAI_PCRC and ESAI_PRRC.
8. Enabled Transmitters/Receivers in ESAI_TCR/ESAI_RCR.

During program execution, all ESAI pins may be defined disconnected, causing the ESAI to stop serial activity and enter the individual reset state.

All status bits of the interface are set to their reset state however, the control bits are not affected. This procedure allows the programmer to reset the ESAI separately from the other internal peripherals. During individual reset, internal DMA accesses to the data registers of the ESAI are not valid and data read is undefined.

The programmer must use an individual ESAI reset when changing the ESAI control registers (except for TEIE, REIE, TLIE, RLIE, TIE, RIE, TE0-TE5, RE0-RE3) to ensure proper operation of the interface.

NOTE

If the ESAI receiver section is already operating with some of the receivers and enabling additional receivers on the fly, that is, without first putting the ESAI receiver in the personal reset state by setting their REx control bits, it will result in erroneous data being received as the first data word for the newly enabled receivers.

52.4.2 ESAI Initialization Examples

52.4.2.1 Initializing the ESAI using Personal Reset

1. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register(ESAI_ECR[0]).
2. The ESAI should be in its personal reset state (ESAI_PCRC = 0x000 and ESAI_PRRC = 0x000). In the personal reset state, both the transmitter and receiver sections of the ESAI are simultaneously reset. The TPR bit in the ESAI_TCR register may be used to reset just the transmitter section. The RPR bit in the ESAI_RCR register may be used to reset just the receiver section.
3. Configure the control registers (ESAI_TCCR, ESAI_TCR, ESAI_RCCR, ESAI_RCR) and ESAI FIFOs configuration Registers (ESAI_TFCR, ESAI_RFCR) according to the operating mode, but do not enable transmitters (TE5-TE0 = 0x0) or receivers (RE3-RE0 = 0x0). It is possible to set the interrupt enable bits which are in use during the operation (no interrupt occurs).
4. Enable the ESAI by setting the ESAI_PCRC and ESAI_PRRC register bits according to pins which are in use during operation.
5. Write initial words to ESAI Transmit Data Register (ESAI_ETDR), at least one word per enabled transmitter slot but as many as desired. For example 4 channels with 2 slot-per-channel are enabled, then 8 words need to be written into ESAI_ETDR. This step is needed even if DMA is used to service the transmitters.
6. Enable the transmitters and receivers.
7. From now on ESAI can be serviced either by polling, interrupts, or DMA.

Operation proceeds as follows:

- For internally generated clock and frame sync, these signals are active immediately after ESAI is enabled (step 4 above).

- Data is received only when one of the receive enable (REx) bits is set and after the occurrence of frame sync signal (either internally or externally generated).
- Data is transmitted only when the transmitter enable (TEx) bit is set and after the occurrence of frame sync signal (either internally or externally generated). The transmitter outputs remain tri-stated after TEx bit is set until the frame sync occurs.

52.4.2.2 Initializing the ESAI Transmitter Section

1. It is assumed that the ESAI is operational; that is, at least one pin is defined as an ESAI pin.
2. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register(ESAI_ECR[0])
3. The transmitter section should be in its individual reset state (TPR = 1) and also reset the ESAI Transmit FIFO (ESAI_TFCR[1] = 1).
4. Configure the control registers ESAI_TCCR and ESAI_TCR according to the operating mode, configure the Transmit FIFO Configuration Register (bring transmit FIFO out of reset, enable Transmit FIFO, enable transmitters, transmit initialization and set watermark). Make sure to clear the transmitter enable bits (TE0-TE5). TPR must remain set.
5. Take the transmitter section out of the individual reset state by clearing TPR.
6. Write initial words to ESAI Transmit Data Register (ESAI_ETDR), at least one word per enabled transmitter slot but as many as desired. For example 4 channels with 2 slot-per-channel are enabled, then 8 words need to be written into ESAI_ETDR
7. Enable the transmitters by setting their TE bits.
8. Data is transmitted only when the transmitter enable (TEx) bit is set and after the occurrence of frame sync signal (either internally or externally generated). The transmitter outputs remain tri-stated after TEx bit is set until the frame sync occurs.
9. From now on the transmitters are operating and can be serviced either by polling, interrupts, or DMA.

52.4.2.3 Initializing the ESAI Receiver Section

1. It is assumed that the ESAI is operational; that is, at least one pin is defined as an ESAI pin.
2. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register (ESAI_ECR[0])
3. The receiver section should be in its individual reset state (RPR = 1) and also reset the ESAI Receive FIFO (ESAI_RFCR[1] = 1).
4. Configure the control registers ESAI_RCCR and ESAI_RCR according to the operating mode, configure the Receive FIFO Configuration Register (bring receive

FIFO out of reset, enable Receive FIFO, receivers, and set watermark). Making sure to clear the receiver enable bits (RE0-RE3). RPR must remain set.
5. Take the receiver section out of the individual reset state by clearing RPR.
6. Enable the receivers by setting their RE bits.
7. From now on the receivers are operating and can be serviced either by polling, interrupts, or DMA.

52.5 ESAI Memory Map/Register Definition

NOTE

To access ESAI interface registers, CCM_CACRR [IP_CLK_DIV] field in CCM should be greater than or equal to 1 (divider by 2).

ESAI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_2000	ESAI Transmit Data Register (ESAI_ETDR)	32	W (always reads 0)	0000_0000h	52.5.1/2904

52.5.1 ESAI Transmit Data Register (ESAI_ETDR)

Address: 4006_2000h base + 0h offset = 4006_2000h

Bit	31–0
R	0
W	ETDR
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

ESAI_ETDR field descriptions

Field	Description
31–0 ETDR	ESAI Transmit Data Register. Writing to this register stores the data written into the ESAI Transmit FIFO. Writing to this register when the Transmit FIFO is full causes the data written to be lost (the existing data within the FIFO is not overwritten). When multiple ESAI transmitters are enabled, the data for each transmitter must be interleaved from lowest transmitter to highest transmitter (for example, if transmitters 0, 2 and 3 are enabled then data must be written as follows: transmitter #0, transmitter #2, transmitter #3, transmitter #0, transmitter #2, transmitter #3, transmitter #0, etc). Data within the ESAI Transmit FIFO is passed to the ESAI transmit shifter registers as defined by the Transmit Word Alignment configuration bits.

52.5.2 ESAI Receive Data Register (ESAI_ERDR)

Address: 4006_2000h base + 4h offset = 4006_2004h

Bit	31–0
R	ERDR
W	
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

ESAI_ERDR field descriptions

Field	Description
31–0 ERDR	ESAI Receive Data Register. Reading this register returns the data within the ESAI Receive FIFO. Reading this register when the Receive FIFO is empty returns the last valid data word. When multiple ESAI receivers are enabled, the data for each receiver is interleaved from lowest receiver to highest receiver (for example, if receivers 0, 2 and 3 are enabled then data is returned as follows: receiver #0, receiver #2, receiver #3, receiver #0, receiver #2, receiver #3, receiver #0, etc). Data is passed from the ESAI receive shift registers to the ESAI Receive FIFO as defined by the Receiver Word Alignment configuration bits either zero or sign-extended based on the Receive Extension control bit.

52.5.3 ESAI Control Register (ESAI_ECR)

Address: 4006_2000h base + 8h offset = 4006_2008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0														ERST	ESAIEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESAI_ECR field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 ETI	EXTAL Transmitter In. Mux EXTAL in place of the High Frequency Transmitter Clock input pin. HCKT can still be used to drive a divided down EXTAL or as GPIO. 0 HCKT pin has normal function. 1 EXTAL muxed into HCKT input.
18 ETO	EXTAL Transmitter Out. Drive the EXTAL input on the High Frequency Transmitter Clock pin. 0 HCKT pin has normal function. 1 EXTAL driven onto HCKT pin.
17 ERI	EXTAL Receiver In. Mux EXTAL in place of the High Frequency Receiver Clock input pin. HCKR can still be used to drive a divided down EXTAL or as GPIO. 0 HCKR pin has normal function. 1 EXTAL muxed into HCKR input.
16 ERO	EXTAL Receiver Out. Drive the EXTAL input on the High Frequency Receiver Clock pin. 0 HCKR pin has normal function. 1 EXTAL driven onto HCKR pin.
15–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 ERST	ESAI Reset. Reset the ESAI core logic (including configuration registers) but not the ESAI FIFOs. 0 ESAI not reset. 1 ESAI reset.
0 ESAIEN	ESAI Enable. Enables/disables the ESAI logic clock. Enable the ESAI before reading or writing other ESAI registers.

Table continues on the next page...

ESAI_ECR field descriptions (continued)

Field	Description
	0 ESAI disabled. 1 ESAI enabled.

52.5.4 ESAI Status Register (ESAI_ESR)

Address: 4006_2000h base + Ch offset = 4006_200Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESAI_ESR field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 TINIT	Transmit Initialization. Indicates that the Transmit FIFO is writing the first word for each enabled transmitter into the Transmit Data Registers. This bit sets when the Transmit FIFO is enabled (provided Transmit Initialization is enabled) and clears after the Transmit Data Registers have been initialized. The Transmit Enable bits in the Transmit Control Register should not be set until this flag has cleared. 0 Transmitter has finished initializing the Transmit Data Registers (or Transmit FIFO is not enabled or Transmit Initialization is not enabled). 1 Transmitter has not finished initializing the Transmit Data Registers.
9 RFF	Receive FIFO Full. Indicates that the number of data words in the Receive FIFO has equaled or exceeded the Receive FIFO Watermark. This flag also drives the ESAI Receiver DMA request line. ESAI FIFO DMA requests see ESAI DMA Requests from the FIFOs. 0 Number of words in Receive FIFO less than Receive FIFO watermark. 1 Number of words in Receive FIFO is equal to or greater than Receive FIFO watermark.
8 TFE	Transmit FIFO Empty. Indicates that the number of empty slots in the Transmit FIFO has met or exceeded the Transmit FIFO Watermark. This flag also drives the ESAI Transmitter DMA request line. ESAI FIFO DMA request see ESAI DMA Requests from the FIFOs. 0 Number of empty slots in Transmit FIFO less than Transmit FIFO watermark. 1 Number of empty slots in Transmit FIFO is equal to or greater than Transmit FIFO watermark.
7 TLS	Transmit Last Slot. Reading this register when TLS is set will negate the Transmit Last Slot interrupt. 0 TLS is not the highest priority active interrupt. 1 TLS is the highest priority active interrupt.

Table continues on the next page...

ESAI_ESR field descriptions (continued)

Field	Description
6 TDE	Transmit Data Exception. 0 TDE is not the highest priority active interrupt. 1 TDE is the highest priority active interrupt.
5 TED	Transmit Even Data. 0 TED is not the highest priority active interrupt. 1 TED is the highest priority active interrupt.
4 TD	Transmit Data. 0 TD is not the highest priority active interrupt. 1 TD is the highest priority active interrupt.
3 RLS	Receive Last Slot. Reading this register when RLS is set will negate the Receive Last Slot interrupt. 0 RLS is not the highest priority active interrupt. 1 RLS is the highest priority active interrupt.
2 RDE	Receive Data Exception. 0 RDE is not the highest priority active interrupt. 1 RDE is the highest priority active interrupt.
1 RED	Receive Even Data. 0 RED is not the highest priority active interrupt. 1 RED is the highest priority active interrupt.
0 RD	Receive Data. 0 RD is not the highest priority active interrupt. 1 RD is the highest priority active interrupt.

52.5.5 Transmit FIFO Configuration Register (ESAI_TFCR)

Address: 4006_2000h base + 10h offset = 4006_2010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												TIEN	TWA[2:0]

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESAI_TFCR field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ESAI_TFCR field descriptions (continued)

Field	Description
19 TIEN	Transmitter Initialization Enable. Enables the initialization of the Transmit Data Registers when the Transmitter FIFO is enabled. TIEN=1 is recommended. 0 Transmit Data Registers are not initialized from the FIFO once the Transmit FIFO is enabled. Software must manually initialize the Transmit Data Registers separately. 1 Transmit Data Registers are initialized from the FIFO once the Transmit FIFO is enabled.
18–16 TWA[2:0]	Transmit Word Alignment. Configures the alignment of the data written into the ESAI Transmit Data Register and then passed to the relevant 24 bit Transmit shift register. 000 MSB of data is bit 31. Data bits 7-0 are ignored when passed to transmit shift register. 001 MSB of data is bit 27. Data bits 3-0 are ignored when passed to transmit shift register. 010 MSB of data is bit 23. 011 MSB of data is bit 19. Bottom 4 bits of transmit shift register are zeroed. 100 MSB of data is bit 15. Bottom 8 bits of transmit shift register are zeroed. 101 MSB of data is bit 11. Bottom 12 bits of transmit shift register are zeroed. 110 MSB of data is bit 7. Bottom 16 bits of transmit shift register are zeroed. 111 MSB of data is bit 3. Bottom 20 bits of transmit shift register are zeroed.
15–8 TFWM[7:0]	Transmit FIFO Watermark. These bits configure the threshold at which the Transmit FIFO Empty flag will set. The TFE is set when the number of empty slots in the Transmit FIFO equal or exceed the selected threshold.
7 TE5	Transmitter #5 FIFO Enable. This bit enables transmitter #5 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #5 is not using the Transmit FIFO. 1 Transmitter #5 is using the Transmit FIFO.
6 TE4	Transmitter #4 FIFO Enable. This bit enables transmitter #4 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #4 is not using the Transmit FIFO. 1 Transmitter #4 is using the Transmit FIFO.
5 TE3	Transmitter #3 FIFO Enable. This bit enables transmitter #3 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #3 is not using the Transmit FIFO. 1 Transmitter #3 is using the Transmit FIFO.
4 TE2	Transmitter #2 FIFO Enable. This bit enables transmitter #2 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #2 is not using the Transmit FIFO. 1 Transmitter #2 is using the Transmit FIFO.
3 TE1	Transmitter #1 FIFO Enable. This bit enables transmitter #1 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #1 is not using the Transmit FIFO. 1 Transmitter #1 is using the Transmit FIFO.
2 TE0	Transmitter #0 FIFO Enable. This bit enables transmitter #0 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #0 is not using the Transmit FIFO. 1 Transmitter #0 is using the Transmit FIFO.

Table continues on the next page...

ESAI_TFCR field descriptions (continued)

Field	Description
1 TFR	Transmit FIFO Reset. This bit resets the Transmit FIFO pointers. 0 Transmit FIFO not reset. 1 Transmit FIFO reset.
0 TFE	Transmit FIFO Enable. This bit enables the use of the Transmit FIFO. 0 Transmit FIFO disabled. 1 Transmit FIFO enabled.

52.5.6 Transmit FIFO Status Register (ESAI_TFSR)

Address: 4006_2000h base + 14h offset = 4006_2014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	NTFO[2:0]			0	NTFI[2:0]			TFCNT[7:0]							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESAI_TFSR field descriptions

Field	Description
31–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–12 NTFO[2:0]	Next Transmitter FIFO Out. Indicates which Transmit Data Register receives the top word of the Transmit FIFO. This will usually equal the lowest enabled transmitter, unless the transmit FIFO is empty. 000 Transmitter #0 receives next word from the Transmit FIFO. 001 Transmitter #1 receives next word from the Transmit FIFO. 010 Transmitter #2 receives next word from the Transmit FIFO. 011 Transmitter #3 receives next word from the Transmit FIFO. 100 Transmitter #4 receives next word from the Transmit FIFO. 101 Transmitter #5 receives next word from the Transmit FIFO. 110 Reserved. 111 Reserved.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 NTFI[2:0]	Next Transmitter FIFO In. Indicates which transmitter receives the next word written to the FIFO. 000 Transmitter #0 receives next word written to the Transmit FIFO. 001 Transmitter #1 receives next word written to the Transmit FIFO.

Table continues on the next page...

ESAI_TFSR field descriptions (continued)

Field	Description
	010 Transmitter #2 receives next word written to the Transmit FIFO. 011 Transmitter #3 receives next word written to the Transmit FIFO. 100 Transmitter #4 receives next word written to the Transmit FIFO. 101 Transmitter #5 receives next word written to the Transmit FIFO. 110 Reserved. 111 Reserved.
7–0 TFCNT[7:0]	Transmit FIFO Counter. These bits indicate the number of data words stored in the Transmit FIFO.

52.5.7 Receive FIFO Configuration Register (ESAI_RFCR)

Address: 4006_2000h base + 18h offset = 4006_2018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	RFWM[7:0]								0		RE3	RE2	RE1	RE0	RFR	RFE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESAI_RFCR field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 REXT	Receive Extension. Enables the receive data to be returned sign extended when the Receive Word Alignment is configured to return data where the MSB is not aligned with bit 31. 0 Receive data is zero extended. 1 Receive data is sign extended.
18–16 RWA[2:0]	Receive Word Alignment. Configures the alignment of the data passed from the relevant 24 bit Receive shift register and read out the ESAI Receive Data Register. 000 MSB of data is at bit 31. Data bits 7-0 are zeroed. 001 MSB of data is at bit 27. Data bits 3-0 are zeroed. 010 MSB of data is at bit 23. 011 MSB of data is at bit 19. Data bits 3-0 from receive shift register are ignored. 100 MSB of data is at bit 15. Data bits 7-0 from receive shift register are ignored. 101 MSB of data is at bit 11. Data bits 11-0 from receive shift register are ignored. 110 MSB of data is at bit 7. Data bits 15-0 from receive shift register are ignored. 111 MSB of data is at bit 3. Data bits 19-0 from receive shift register are ignored.

Table continues on the next page...

ESAI_RFCR field descriptions (continued)

Field	Description
15–8 RFWM[7:0]	Receive FIFO Watermark. These bits configure the threshold at which the Receive FIFO Full flag will set. The RFF is set when the number of words in the Receive FIFO equal or exceed the selected threshold. It can be set to a non-zero value.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 RE3	Receiver #3 FIFO Enable. This bit enables receiver #3 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #3 is not using the Receive FIFO. 1 Receiver #3 is using the Receive FIFO.
4 RE2	Receiver #2 FIFO Enable. This bit enables receiver #2 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #2 is not using the Receive FIFO. 1 Receiver #2 is using the Receive FIFO.
3 RE1	Receiver #1 FIFO Enable. This bit enables receiver #1 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #1 is not using the Receive FIFO. 1 Receiver #1 is using the Receive FIFO.
2 RE0	Receiver #0 FIFO Enable. This bit enables receiver #0 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #0 is not using the Receive FIFO. 1 Receiver #0 is using the Receive FIFO.
1 RFR	Receive FIFO Reset. This bit resets the Receive FIFO pointers. 0 Receive FIFO not reset. 1 Receive FIFO reset.
0 RFE	Receive FIFO Enable. This bit enables the use of the Receive FIFO. 0 Receive FIFO disabled. 1 Receive FIFO enabled.

52.5.8 Receive FIFO Status Register (ESAI_RFSR)

Address: 4006_2000h base + 1Ch offset = 4006_201Ch

ESAI_RFSR field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–12 NRFI[1:0]	Next Receiver FIFO In. Indicates which Receiver Data Register the Receive FIFO will load next. This will usually equal the lowest enabled receiver, unless the receive FIFO is full. 00 Receiver #0 returns next word to the Receive FIFO. 01 Receiver #1 returns next word to the Receive FIFO. 10 Receiver #2 returns next word to the Receive FIFO. 11 Receiver #3 returns next word to the Receive FIFO.
11–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 NRFO[1:0]	Next Receiver FIFO Out. Indicates which receiver returns the top word of the Receive FIFO. 00 Receiver #0 returns next word from the Receive FIFO. 01 Receiver #1 returns next word from the Receive FIFO. 10 Receiver #2 returns next word from the Receive FIFO. 11 Receiver #3 returns next word from the Receive FIFO.
7–0 RFCNT[7:0]	Receive FIFO Counter. These bits indicate the number of data words stored in the Receive FIFO.

52.5.9 Transmit Data Register n (ESAI_TX*n*)

ESAI_TX5, ESAI_TX4, ESAI_TX3, ESAI_TX2, ESAI_TX1 and ESAI_TX0 are 32-bit write-only registers. Data to be transmitted is written into these registers and is automatically transferred to the transmit shift registers (Figure 52-2 and Figure 52-3). The data written (8, 12, 16, 20, or 24 bits) should occupy the most significant portion of the TXn according to the ALC control bit setting. The unused bits (least significant portion and the 8 most significant bits when ALC=1) of the TXn are don't care bits. The Core is interrupted whenever the TXn becomes empty if the transmit data register empty interrupt has been enabled.

Address: 4006_2000h base + 80h offset + (4d × i), where i=0d to 5d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESAI_TSR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–0 TSR[23:0]	The write-only Transmit Slot Register (ESAI_TSR) is effectively a null data register that is used when the data is not to be transmitted in the available transmit time slot. The transmit data pins of all the enabled transmitters are in the high-impedance state for the respective time slot where TSR has been written. The Transmitter External Buffer Enable pin (FSR pin when SYN=1, TEBE=1, RFSD=1) disables the external buffers during the slot when the ESAI_TSR register has been written.

52.5.11 Receive Data Register n (ESAI_RX*n*)

ESAI_RX3, ESAI_RX2, ESAI_RX1, and ESAI_RX0 are 32-bit read-only registers that accept data from the receive shift registers when they become full (Figure 52-2 and Figure 52-3). The data occupies the most significant portion of the receive data registers, according to the ALC control bit setting. The unused bits (least significant portion and 8 most significant bits when ALC=1) read as zeros. The Core is interrupted whenever RXn becomes full if the associated interrupt is enabled.

Address: 4006_2000h base + A0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

52.5.12 Serial Audio Interface Status Register (ESAI_SAISR)

The Status Register (ESAI_SAISR) is a read-only status register used by the ARM Core to read the status and serial input flags of the ESAI.

Address: 4006_2000h base + CCh offset = 4006_20CCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESAI_SAISR field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 TODFE	ESAI_SAISR Transmit Odd-Data Register Empty. When set, TODFE indicates that the enabled transmitter data registers became empty at the beginning of an odd time slot. Odd time slots are all odd-numbered slots (1, 3, 5, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. This flag is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TODFE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TODE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TODFE is set. Hardware, software, ESAI individual reset clear TODFE.
16 TEDE	ESAI_SAISR Transmit Even-DataRegister Empty. When set, TEDE indicates that the enabled transmitter data registers became empty at the beginning of an even time slot. Even time slots are all even-numbered slots (0, 2, 4, 6, etc.). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. The zero time slot is considered even. This flag is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TEDE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TEDE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TEDE is set. Hardware, software, ESAI individual reset clear TEDE.
15 TDE	ESAI_SAISR Transmit Data Register Empty. TDE is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TDE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (ESAI_TSR). TDE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TDE is set. Hardware, software, ESAI individual reset clear TDE.
14 TUE	ESAI_SAISR Transmit Underrun Error Flag. TUE is set when at least one of the enabled serial transmit shift registers is empty (no new data to be transmitted) and a transmit time slot occurs. When a transmit underrun error occurs, the previous data (which is still present in the TX registers that were not written) is retransmitted. If TEIE is set, an ESAI transmit data with exception (underrun error) interrupt request is issued when TUE is set. Hardware, software, ESAI individual reset clear TUE. TUE is also cleared by reading the ESAI_SAISR with TUE set, followed by writing to all the enabled transmit data registers or to ESAI_TSR.
13 TFS	ESAI_SAISR Transmit Frame Sync Flag. When set, TFS indicates that a transmit frame sync occurred in the current time slot. TFS is set at the start of the first time slot in the frame and cleared during all other time slots. Data written to a transmit data register during the time slot when TFS is set is transmitted (in network mode), if the transmitter is enabled, during the second time slot in the frame. TFS is useful in network mode to identify the start of a frame. TFS is cleared by hardware, software, ESAI individual reset. TFS is valid only if at least one transmitter is enabled, that is, one or more of TE0, TE1, TE2, TE3, TE4 and TE5 are set. (In normal mode, TFS always reads as a one when transmitting data because there is only one time slot per frame - the "frame sync" time slot)
12–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 RODF	ESAI_SAISR Receive Odd-Data Register Full. When set, RODF indicates that the received data in the receive data registers of the enabled receivers have arrived during an odd time slot when operating in the network mode. Odd time slots are all odd-numbered slots (1, 3, 5, and so on). Time slots are numbered

Table continues on the next page...

ESAI_SAISR field descriptions (continued)

Field	Description
	from zero to N-1, where N is the number of time slots in the frame. RODF is set when the contents of the receive shift registers are transferred to the receive data registers. RODF is cleared when the Core reads all the enabled receive data registers or cleared by hardware, software, ESAI individual resets.
9 REDF	ESAI_SAISR Receive Even-Data Register Full. When set, REDF indicates that the received data in the receive data registers of the enabled receivers have arrived during an even time slot when operating in the network mode. Even time slots are all even-numbered slots (0, 2, 4, 6, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. The zero time slot is considered even. REDF is set when the contents of the receive shift registers are transferred to the receive data registers. REDF is cleared when the Core reads all the enabled receive data registers or cleared by hardware, software, ESAI individual resets. If REDIE is set, an ESAI receive even slot data interrupt request is issued when REDF is set.
8 RDF	ESAI_SAISR Receive Data Register Full. RDF is set when the contents of the receive shift register of an enabled receiver is transferred to the respective receive data register. RDF is cleared when the Core reads the receive data register of all enabled receivers or cleared by hardware, software, ESAI individual reset. If RIE is set, an ESAI receive data interrupt request is issued when RDF is set.
7 ROE	ESAI_SAISR Receive Overrun Error Flag. The ROE flag is set when the serial receive shift register of an enabled receiver is full and ready to transfer to its receiver data register (RXn) and the register is already full (RDF=1). If REIE is set, an ESAI receive data with exception (overrun error) interrupt request is issued when ROE is set. Hardware, software, ESAI individual reset clear ROE. ROE is also cleared by reading the SAISR with ROE set, followed by reading all the enabled receive data registers.
6 RFS	ESAI_SAISR Receive Frame Sync Flag. When set, RFS indicates that a receive frame sync occurred during reception of the words in the receiver data registers. This indicates that the data words are from the first slot in the frame. When RFS is clear and a word is received, it indicates (only in the network mode) that the frame sync did not occur during reception of that word. RFS is cleared by hardware, software, ESAI individual reset. RFS is valid only if at least one of the receivers is enabled (REx=1). (In normal mode, RFS always reads as a one when reading data because there is only one time slot per frame - the "frame sync" time slot)
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 IF2	ESAI_SAISR Serial Input Flag 2. The IF2 bit is enabled only when the HCKR pin is defined as ESAI in the Port Control Register, SYN=1 and RHCKD=0, indicating that HCKR is an input flag and the synchronous mode is selected. Data present on the HCKR pin is latched during reception of the first received data bit after frame sync is detected. The IF2 bit is updated with this data when the receive shift registers are transferred into the receiver data registers. IF2 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF2.
1 IF1	ESAI_SAISR Serial Inout Flag 1. The IF1 bit is enabled only when the FSR pin is defined as ESAI in the Port Control Register, SYN =1, RFSD=0 and TEBE=0, indicating that FSR is an input flag and the synchronous mode is selected. Data present on the FSR pin is latched during reception of the first received data bit after frame sync is detected. The IF1 bit is updated with this data when the receiver shift registers are transferred into the receiver data registers. IF1 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF1.
0 IF0	ESAI_SAISR Serial Input Flag 0. The IF0 bit is enabled only when the SCKR pin is defined as ESAI in the Port Control Register, SYN=1 and RCKD=0, indicating that SCKR is an input flag and the synchronous mode is selected. Data present on the SCKR pin is latched during reception of the first received data bit after frame sync is detected. The IF0 bit is updated with this data when the receiver shift registers are transferred into the receiver data registers. IF0 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF0.

52.5.13 Serial Audio Interface Control Register (ESAI_SAICR)

The read/write Common Control Register (ESAI_SAICR) contains control bits for functions that affect both the receive and transmit sections of the ESAI.

ESAI_SAICR field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 ALC	ESAI_SAICR Alignment Control. The ESAI is designed for 24-bit fractional data, thus shorter data words are left aligned to the MSB (bit 23). Some applications use 16-bit fractional data. In those cases, shorter data words may be left aligned to bit 15. The Alignment Control (ALC) bit supports these applications. If ALC is set, transmitted and received words are left aligned to bit 15 in the transmit and receive shift registers. If ALC is cleared, transmitted and received word are left aligned to bit 23 in the transmit and receive shift registers. While ALC is set, 20-bit and 24-bit words may not be used, and word length control should specify 8-, 12-, or 16-bit words; otherwise, results are unpredictable.
7 TEBE	ESAI_SAICR Transmit External Buffer Enable. The Transmitter External Buffer Enable (TEBE) bit controls the function of the FSR pin when in the synchronous mode. If the ESAI is configured for operation in the synchronous mode (SYN=1), and TEBE is set while FSR pin is configured as an output (RFSD=1), the FSR pin functions as the transmitter external buffer enable control to enable the use of an external buffers on the transmitter outputs. If TEBE is cleared, the FSR pin functions as the serial I/O flag 1. See Port C Control Register for a summary of the effects of TEBE on the FSR pin.
6 SYN	ESAI_SAICR Synchronous Mode Selection. The Synchronous Mode Selection (SYN) bit controls whether the receiver and transmitter sections of the ESAI operate synchronously or asynchronously with respect to each other (see Port C Control Register). When SYN is cleared, the asynchronous mode is chosen and independent clock and frame sync signals are used for the transmit and receive sections. When SYN is set, the synchronous mode is chosen and the transmit and receive sections use common clock and frame sync signals. When in the synchronous mode (SYN=1), the transmit and receive sections use the transmitter section clock generator as the source of the clock and frame sync for both sections. Also, the receiver clock pins SCKR, FSR and HCKR now operate as I/O flags. Refer to Table 52-38, Table 52-39, and Table 52-40 for the effects of SYN on the receiver clock pins.
5–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 OF2	ESAI_SAICR Serial Output Flag 2. The Serial Output Flag 2 (OF2) is a data bit used to hold data to be send to the OF2 pin. When the ESAI is in the synchronous clock mode (SYN=1), the HCKR pin is configured as the ESAI flag 2. If the receiver high frequency clock direction bit (RHCKD) is set, the HCKR pin is the output flag OF2, and data present in the OF2 bit is written to the OF2 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.
1 OF1	ESAI_SAICR Serial Output Flag 1. The Serial Output Flag 1 (OF1) is a data bit used to hold data to be send to the OF1 pin. When the ESAI is in the synchronous clock mode (SYN=1), the FSR pin is configured as the ESAI flag 1. If the receiver frame sync direction bit (RFSD) is set and the TEBE bit is cleared, the FSR pin is the output flag OF1, and data present in the OF1 bit is written to the OF1 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.

Table continues on the next page...

ESAI_SAICR field descriptions (continued)

Field	Description
0 OF0	ESAI_SAICR Serial Output Flag 0. The Serial Output Flag 0 (OF0) is a data bit used to hold data to be send to the OF0 pin. When the ESAI is in the synchronous clock mode (SYN=1), the SCKR pin is configured as the ESAI flag 0. If the receiver serial clock direction bit (RCKD) is set, the SCKR pin is the output flag OF0, and data present in the OF0 bit is written to the OF0 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.

52.5.14 Transmit Control Register (ESAI_TCR)

The read/write Transmit Control Register (ESAI_TCR) controls the ESAI transmitter section. Interrupt enable bits for the transmitter section are provided in this control register. Operating modes are also selected in this register.

ESAI_TCR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 TLIE	ESAI_TCR Transmit Last Slot Interrupt Enable. TLIE enables an interrupt at the beginning of last slot of a frame in network mode. When TLIE is set the Core is interrupted at the start of the last slot in a frame in network mode regardless of the transmit mask register setting. When TLIE is cleared the transmit last slot interrupt is disabled. TLIE is disabled when TDC[4:0]=0x00000 (on-demand mode). The use of the transmit last slot interrupt is described in ESAI Interrupt Requests.
22 TIE	ESAI_TCR Transmit Interrupt Enable. The Core is interrupted when TIE and the TDE flag in the ESAI_SAISR status register are set. When TIE is cleared, this interrupt is disabled. Writing data to all the data registers of the enabled transmitters or to ESAI_TSR clears TDE, thus clearing the interrupt. Transmit interrupts with exception have higher priority than normal transmit data interrupts, therefore if exception occurs (TUE is set) and TEIE is set, the ESAI requests an ESAI transmit data with exception interrupt from the interrupt controller.
21 TEDIE	ESAI_TCR Transmit Even Slot Data Interrupt Enable. The TEDIE control bit is used to enable the transmit even slot data interrupts. If TEDIE is set, the transmit even slot data interrupts are enabled. If TEDIE is cleared, the transmit even slot data interrupts are disabled. A transmit even slot data interrupt request is generated if TEDIE is set and the TEDE status flag in the ESAI_SAISR status register is set. Even time slots are all even-numbered time slots (0, 2, 4, etc.) when operating in network mode. The zero time slot in the frame is marked by the frame sync signal and is considered to be even. Writing data to all the data registers of the enabled transmitters or to ESAI_TSR clears the TEDE flag, thus servicing the interrupt. Transmit interrupts with exception have higher priority than transmit even slot data interrupts, therefore if exception occurs (TUE is set) and TEIE is set, the ESAI requests an ESAI transmit data with exception interrupt from the interrupt controller.
20 TEIE	ESAI_TCR Transmit Exception Interrupt Enable. When TEIE is set, the Core is interrupted when both TDE and TUE in the ESAI_SAISR status register are set. When TEIE is cleared, this interrupt is disabled. Reading the ESAI_SAISR status register followed by writing to all the data registers of the enabled transmitters clears TUE, thus clearing the pending interrupt.
19 TPR	ESAI_TCR Transmit Section Personal Reset. The TPR control bit is used to put the transmitter section of the ESAI in the personal reset state. The receiver section is not affected. When TPR is cleared, the transmitter section may operate normally. When TPR is set, the transmitter section enters the personal reset state immediately. When in the personal reset state, the status bits are reset to the same state as after hardware reset. The control bits are not affected by the personal reset state. The transmitter data pins are tri-stated while in the personal reset state; if a stable logic level is desired, the transmitter data pins should be defined as GPIO outputs, or external pull-up or pull-down resistors should be used. The

ESAI_TCR field descriptions (continued)

Field	Description
	transmitter clock outputs drive zeroes while in the personal reset state. Note that to leave the personal reset state by clearing TPR, the procedure described in ESAI Initialization Examples should be followed.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 PADC	ESAI_TCR Transmit Zero Padding Control. When PADC is cleared, zero padding is disabled. When PADC is set, zero padding is enabled. PADC, in conjunction with the TWA control bit, determines the way that padding is done for operating modes where the word length is less than the slot length. See the TWA bit description in bit 7 for more details. Because the data word is shorter than the slot length, the data word is extended until achieving the slot length, according to the following rule: If the data word is left-aligned (TWA=0), and zero padding is disabled (PADC=0), the last data bit is repeated after the data word has been transmitted. If zero padding is enabled (PADC=1), zeroes are transmitted after the data word has been transmitted. If the data word is right-aligned (TWA=1), and zero padding is disabled (PADC=0), the first data bit is repeated before the transmission of the data word. If zero padding is enabled (PADC=1), zeroes are transmitted before the transmission of the data word.
16 TFSR	ESAI_TCR Transmit Frame Sync Relative Timing. TFSR determines the relative timing of the transmit frame sync signal as referred to the serial data lines, for a word length frame sync only (TFSL=0). When TFSR is cleared the word length frame sync occurs together with the first bit of the data word of the first slot. When TFSR is set the word length frame sync starts one serial clock cycle earlier, that is, together with the last bit of the previous data word.
15 TFSL	ESAI_TCR Transmit Frame Sync Length. The TFSL bit selects the length of frame sync to be generated or recognized. If TFSL is cleared, a word-length frame sync is selected. If TFSL is set, a 1-bit clock period frame sync is selected. See Figure 1-21 for examples of frame length selection.
14–10 TSWS[14:10]	ESAI_TCR Tx Slot and Word Length Select (TSWS4-TSWS0). The TSWS4-TSWS0 bits are used to select the length of the slot and the length of the data words being transferred through the ESAI. The word length must be equal to or shorter than the slot length. The possible combinations are shown in Table 52-30. See also the ESAI data path programming model in Figure 52-2 and Figure 52-3.
9–8 TMOD[9:8]	ESAI_TCR Transmit Network Mode Control (TMOD1-TMOD0). The TMOD1 and TMOD0 bits are used to define the network mode of ESAI transmitters, as shown in Table 52-30. In the normal mode, the frame rate divider determines the word transfer rate - one word is transferred per frame sync during the frame sync time slot, as shown in Figure 52-29. In network mode, it is possible to transfer a word for every time slot, as shown in Figure 52-29. For further details, refer to Modes of Operation In order to comply with AC-97 specifications, TSWS4-TSWS0 should be set to 00011 (20-bit slot, 20-bit word length), TFSL and TFSR should be cleared, and TDC4-TDC0 should be set to 0x0C (13 words in frame). If TMOD[1:0]=0b11 and the above recommendations are followed, the first slot and word will be 16 bits long, and the next 12 slots and words will be 20 bits long, as required by the AC97 protocol.
7 TWA	ESAI_TCR Transmit Word Alignment Control. The Transmitter Word Alignment Control (TWA) bit defines the alignment of the data word in relation to the slot. This is relevant for the cases where the word length is shorter than the slot length. If TWA is cleared, the data word is left-aligned in the slot frame during transmission. If TWA is set, the data word is right-aligned in the slot frame during transmission. Because the data word is shorter than the slot length, the data word is extended until achieving the slot length, according to the following rule: If the data word is left-aligned (TWA=0), and zero padding is disabled (PADC=0), the last data bit is repeated after the data word has been transmitted. If zero padding is enabled (PADC=1), zeroes are transmitted after the data word has been transmitted. If the data word is right-aligned (TWA=1), and zero padding is disabled (PADC=0), the first data bit is repeated before the transmission of the data word. If zero padding is enabled (PADC=1), zeroes are transmitted before the transmission of the data word.

ESAI_TCR field descriptions (continued)

Field	Description
6 TSHFD	ESAI_TCR Transmit Shift Direction. The TSHFD bit causes the transmit shift registers to shift data out MSB first when TSHFD equals zero or LSB first when TSHFD equals one (see Figure 52-2 and Figure 52-3 .
5 TE5	ESAI_TCR ESAI Transmit 5 Enable. TE5 enables the transfer of data from ESAI_TX5 to the transmit shift register #5. When TE5 is set and a frame sync is detected, the transmit #5 portion of the ESAI is enabled for that frame. When TE5 is cleared, the transmitter #5 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX5 when TE5 is cleared but the data is not transferred to the transmit shift register #5. The SDO5/SDI0 pin is the data input pin for ESAI_RX0 if TE5 is cleared and RE0 in the ESAI_RCR register is set. If both RE0 and TE5 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE0 and TE5 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE5 and setting it again disables the transmitter #5 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO5/SDI0 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE5 can be left enabled.
4 TE4	ESAI_TCR ESAI Transmit 4 Enable. TE4 enables the transfer of data from ESAI_TX4 to the transmit shift register #4. When TE4 is set and a frame sync is detected, the transmit #4 portion of the ESAI is enabled for that frame. When TE4 is cleared, the transmitter #4 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX4 when TE4 is cleared but the data is not transferred to the transmit shift register #4. The SDO4/SDI1 pin is the data input pin for ESAI_RX1 if TE4 is cleared and RE1 in the RCR register is set. If both RE1 and TE4 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE1 and TE4 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE4 and setting it again disables the transmitter #4 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO4/SDI1 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE4 can be left enabled.
3 TE3	ESAI_TCR ESAI Transmit 3 Enable. TE3 enables the transfer of data from ESAI_TX3 to the transmit shift register #3. When TE3 is set and a frame sync is detected, the transmit #3 portion of the ESAI is enabled for that frame. When TE3 is cleared, the transmitter #3 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to ESAI_TX3 when TE3 is cleared but the data is not transferred to the transmit shift register #3. The SDO3/SDI2 pin is the data input pin for ESAI_RX2 if TE3 is cleared and RE2 in the ESAI_RCR register is set. If both RE2 and TE3 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE2 and TE3 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE3 and setting it again disables the transmitter #3 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO3/SDI2 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE3 can be left enabled.
2 TE2	ESAI_TCR ESAI Transmit 2 Enable. TE2 enables the transfer of data from ESAI_TX2 to the transmit shift register #2. When TE2 is set and a frame sync is detected, the transmit #2 portion of the ESAI is enabled for that frame. When TE2 is cleared, the transmitter #2 is disabled after completing transmission of data

Table continues on the next page...

ESAI_TCR field descriptions (continued)

Field	Description
	currently in the ESAI transmit shift register. Data can be written to ESAI_TX2 when TE2 is cleared but the data is not transferred to the transmit shift register #2. The SDO2/SDI3 pin is the data input pin for ESAI_RX3 if TE2 is cleared and RE3 in the ESAI_RCR register is set. If both RE3 and TE2 are cleared, the transmitter and receiver are disabled, and the pin is tri-stated. Both RE3 and TE2 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE2 and setting it again disables the transmitter #2 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO2/SDI3 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE2 can be left enabled.
1 TE1	ESAI_TCR ESAI Transmit 1 Enable. TE1 enables the transfer of data from TX1 to the transmit shift register #1. When TE1 is set and a frame sync is detected, the transmit #1 portion of the ESAI is enabled for that frame. When TE1 is cleared, the transmitter #1 is disabled after completing transmission of data currently in the ESAI transmit shift register. The SDO1 output is tri-stated, and any data present in TX1 is not transmitted, that is, data can be written to TX1 with TE1 cleared, but data is not transferred to the transmit shift register #1. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE1 and setting it again disables the transmitter #1 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO1 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE1 can be left enabled.
0 TE0	ESAI_TCR ESAI Transmit 0 Enable. TE0 enables the transfer of data from ESAI_TX0 to the transmit shift register #0. When TE0 is set and a frame sync is detected, the transmit #0 portion of the ESAI is enabled for that frame. When TE0 is cleared, the transmitter #0 is disabled after completing transmission of data currently in the ESAI transmit shift register. The SDO0 output is tri-stated, and any data present in ESAI_TX0 is not transmitted, that is, data can be written to ESAI_TX0 with TE0 cleared, but data is not transferred to the transmit shift register #0. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE0 and setting it again disables the transmitter #0 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO0 pin remains in the high-impedance state.The on-demand mode transmit enable sequence can be the same as the normal mode, or TE0 can be left enabled.

52.5.15 Transmit Clock Control Register (ESAI_TCCR)

The read/write Transmitter Clock Control Register (ESAI_TCCR) controls the ESAI transmitter clock generator bit and frame sync rates, the bit clock and high frequency clock sources and the directions of the HCKT, FST and SCKT signals. In the synchronous mode (SYN=1), the bit clock defined for the transmitter determines the receiver bit clock as well. ESAI_TCCR also controls the number of words per frame for the serial data. Hardware and software reset clear all the bits of the ESAI_TCCR register.

Care should be taken in asynchronous mode whenever the frame sync clock (FSR, FST) is not sourced directly from its associated bit clock (SCKR, SCKT). Proper phase relationships must be maintained between these clocks in order to guarantee proper operation of the ESAI.

NOTE

ARM Core clock is ipg_clk_esai in block ESAI which is from CCM's ahb_clk_root.

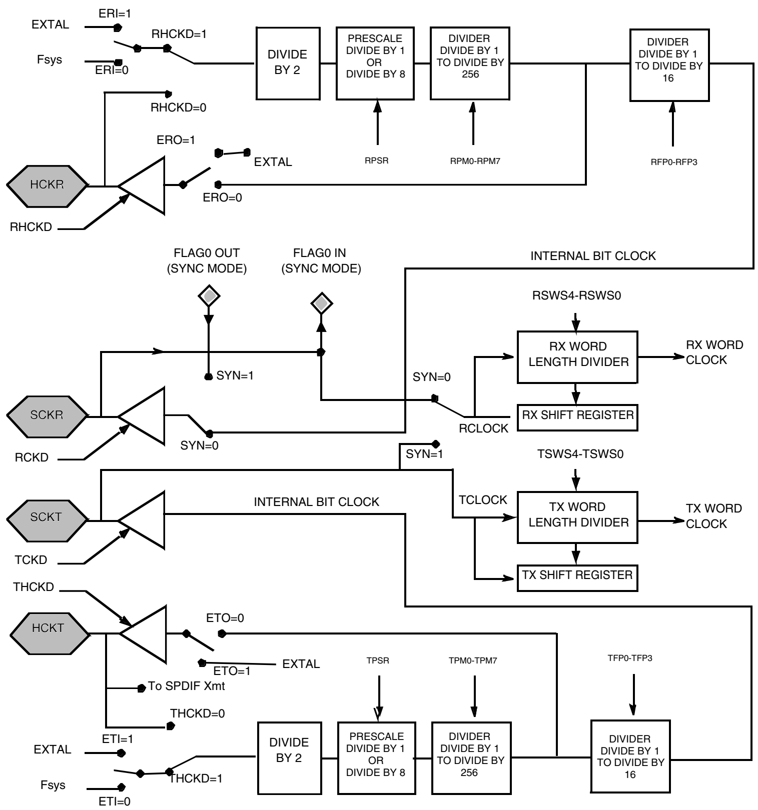

Figure 52-32. ESAI Clock Generator Functional Block Diagram

NOTE

1. ETI, ETO, ERI and ERO bit descriptions are covered in ESAI Control Register (ESAI_ECR). 2. Fsys is the ESAI system 133 MHz clock. 3. EXTAL is the on-chip clock sources other than ESAI system 133MHz clock.

ESAI_TCCR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 THCKD	ESAI_TCCR Transmit High Frequency Clock Direction. THCKD controls the direction of the HCKT pin. When THCKD is cleared, HCKT is an input; when THCKD is set, HCKT is an output (see Table 52-3).
22 TFSD	ESAI_TCCR Transmit Frame Sync Signal Direction. TFSD controls the direction of the FST pin. When TFSD is cleared, FST is an input; when TFSD is set, FST is an output (see Table 52-3).
21 TCKD	ESAI_TCCR Transmit Clock Source Direction. The Transmitter Clock Source Direction (TCKD) bit selects the source of the clock signal used to clock the transmit shift registers in the asynchronous mode (SYN=0) and the transmit shift registers and the receive shift registers in the synchronous mode (SYN=1). When TCKD is set, the internal clock source becomes the bit clock for the transmit shift registers and word length divider and is the output on the SCKT pin. When TCKD is cleared, the clock source is external; the internal clock generator is disconnected from the SCKT pin, and an external clock source may drive this pin (see Table 52-3).
20 THCKP	ESAI_TCCR Transmit High Frequency Clock Polarity. The Transmitter High Frequency Clock Polarity (THCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If THCKP is cleared the data and the frame sync are clocked out on the rising edge of the transmit high frequency bit clock and latched in on the falling edge of the transmit bit clock. If THCKP is set the falling edge of the transmit clock is used to clock the data out and frame sync and the rising edge of the transmit clock is used to latch the data and frame sync in.
19 TFSP	ESAI_TCCR Transmit Frame Sync Polarity. The Transmitter Frame Sync Polarity (TFSP) bit determines the polarity of the transmit frame sync signal. When TFSP is cleared, the frame sync signal polarity is positive, that is, the frame start is indicated by a high level on the frame sync pin. When TFSP is set, the frame sync signal polarity is negative, that is, the frame start is indicated by a low level on the frame sync pin.
18 TCKP	ESAI_TCCR Transmit Clock Polarity. The Transmitter Clock Polarity (TCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If TCKP is cleared the data and the frame sync are clocked out on the rising edge of the transmit bit clock and latched in on the falling edge of the transmit bit clock. If TCKP is set the falling edge of the transmit clock is used to clock the data out and frame sync and the rising edge of the transmit clock is used to latch the data and frame sync in.
17–14 TFP[3:0]	ESAI_TCCR Tx High Frequency Clock Divider. The TFP3-TFP0 bits control the divide ratio of the transmitter high frequency clock to the transmitter serial bit clock when the source of the high frequency clock and the bit clock is the internal ARM Core clock. When the HCKT input is being driven from an external high frequency clock, the TFP3-TFP0 bits specify an additional division ratio in the clock divider

Table continues on the next page...

ESAI_TCCR field descriptions (continued)

Field	Description
	chain. Table 52-32 shows the specification for the divide ratio. Figure 52-32 shows the ESAI high frequency clock generator functional diagram.
13–9 TDC[4:0]	ESAI_TCCR Tx Frame Rate Divider Control. The TDC4-TDC0 bits control the divide ratio for the programmable frame rate dividers used to generate the transmitter frame clocks. In network mode, this ratio may be interpreted as the number of words per frame minus one. The divide ratio may range from 2 to 32 (TDC[4:0]=0x00001 to 0x11111) for network mode. A divide ratio of one (TDC[4:0]=0x00000) in network mode is a special case (on-demand mode). In normal mode, this ratio determines the word transfer rate. The divide ratio may range from 1 to 32 (TDC[4:0]=0x00000 to 0x11111) for normal mode. In normal mode, a divide ratio of 1 (TDC[4:0]=0x00000) provides continuous periodic data word transfers. A bit-length frame sync (TFSL=1) must be used in this case. The ESAI frame sync generator functional diagram is shown in Figure 52-33
8 TPSR	ESAI_TCCR Transmit Prescaler Range. The TPSR bit controls a fixed divide-by-eight prescaler in series with the variable prescaler. This bit is used to extend the range of the prescaler for those cases where a slower bit clock is desired. When TPSR is set, the fixed prescaler is bypassed. When TPSR is cleared, the fixed divide-by-eight prescaler is operational (see Figure 52-32). The maximum internally generated bit clock frequency is Fsys/4; the minimum internally generated bit clock frequency is Fsys/(2 x 8 x 256 x 16)=Fsys/65536. (Do not use the combination TPSR=1, TPM7-TPM0=0x00, and TFP3-TFP0=0x0 which causes synchronization problems when using the internal ARM Core clock as source (TCKD=1 or THCKD=1))
7–0 TPM[7:0]	ESAI_TCCR Transmit Prescale Modulus Select. The TPM7-TPM0 bits specify the divide ratio of the prescale divider in the ESAI transmitter clock generator. A divide ratio from 1 to 256 (TPM[7:0]=0x00 to 0xFF) may be selected. The bit clock output is available at the transmit serial bit clock (SCKT) pin. The bit clock output is also available internally for use as the bit clock to shift the transmit and receive shift registers. The ESAI transmit clock generator functional diagram is shown in Figure 52-32.

52.5.16 Receive Control Register (ESAI_RCR)

The read/write Receive Control Register (ESAI_RCR) controls the ESAI receiver section. Interrupt enable bits for the receivers are provided in this control register. The receivers are enabled in this register (0,1,2 or 3 receivers can be enabled) if the input data pin is not used by a transmitter. Operating modes are also selected in this register.

ESAI_RCR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RLIE	ESAI_RCR Receive Last Slot Interrupt Enable. RLIE enables an interrupt after the last slot of a frame ended in network mode only. When RLIE is set the Core is interrupted after the last slot in a frame ended regardless of the receive mask register setting. When RLIE is cleared the receive last slot interrupt is disabled. Hardware and software reset clear RLIE. RLIE is disabled when RDC[4:0]=00000 (on-demand mode). The use of the receive last slot interrupt is described in ESAI Interrupt Requests.
22 RIE	ESAI_RCR Receive Interrupt Enable. The Core is interrupted when RIE and the RDF flag in the ESAI_SAISR status register are set. When RIE is cleared, this interrupt is disabled. Reading the receive data registers of the enabled receivers clears RDF, thus clearing the interrupt. Receive interrupts with exception have higher priority than normal receive data interrupts, therefore if exception occurs (ROE is set) and REIE is set, the ESAI requests an ESAI receive data with exception interrupt from the interrupt controller.
21 REDIE	ESAI_RCR Receive Even Slot Data Interrupt Enable. The REDIE control bit is used to enable the receive even slot data interrupts. If REDIE is set, the receive even slot data interrupts are enabled. If REDIE is cleared, the receive even slot data interrupts are disabled. A receive even slot data interrupt request is generated if REDIE is set and the REDF status flag in the ESAI_SAISR status register is set. Even time slots are all even-numbered time slots (0, 2, 4, etc.) when operating in network mode. The zero time slot is marked by the frame sync signal and is considered to be even. Reading all the data registers of the enabled receivers clears the REDF flag, thus servicing the interrupt. Receive interrupts with exception have higher priority than receive even slot data interrupts, therefore if exception occurs (ROE is set) and REIE is set, the ESAI requests an ESAI receive data with exception interrupt from the interrupt controller.
20 REIE	ESAI_RCR Receive Exception Interrupt Enable. When REIE is set, the Core is interrupted when both RDF and ROE in the ESAI_SAISR status register are set. When REIE is cleared, this interrupt is disabled. Reading the ESAI_SAISR status register followed by reading the enabled receivers data registers clears ROE, thus clearing the pending interrupt.
19 RPR	ESAI_RCR Receiver Section Personal Reset. The RPR control bit is used to put the receiver section of the ESAI in the personal reset state. The transmitter section is not affected. When RPR is cleared, the receiver section may operate normally. When RPR is set, the receiver section enters the personal reset state immediately. When in the personal reset state, the status bits are reset to the same state as after hardware reset.The control bits are not affected by the personal reset state.The receiver data pins are disconnected while in the personal reset state.

Table continues on the next page...

ESAI_RCR field descriptions (continued)

Field	Description
	NOTE: To leave the personal reset state by clearing RPR, the procedure described in ESAI Initialization Examples should be followed.
18–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 RFSR	ESAI_RCR Receiver Frame Sync Relative Timing. RFSR determines the relative timing of the receive frame sync signal as referred to the serial data lines, for a word length frame sync only. When RFSR is cleared the word length frame sync occurs together with the first bit of the data word of the first slot. When RFSR is set the word length frame sync starts one serial clock cycle earlier, that is, together with the last bit of the previous data word.
15 RFSL	ESAI_RCR Receiver Frame Sync Length. The RFSL bit selects the length of the receive frame sync to be generated or recognized. If RFSL is cleared, a word-length frame sync is selected. If RFSL is set, a 1-bit clock period frame sync is selected. Refer to Figure 52-30 for examples of frame length selection.
14–10 RSWS[4:0]	ESAI_RCR Receiver Slot and Word Select. The RSWS4-RSWS0 bits are used to select the length of the slot and the length of the data words being received through the ESAI. The word length must be equal to or shorter than the slot length. The possible combinations are shown in Table 52-35. See also the ESAI data path programming model in Figure 52-2 and Figure 52-3.
9–8 RMOD[1:0]	ESAI_RCR Receiver Network Mode Control. The RMOD1 and RMOD0 bits are used to define the network mode of the ESAI receivers, as shown in Table 52-34. In the normal mode, the frame rate divider determines the word transfer rate - one word is transferred per frame sync during the frame sync time slot, as shown in Figure 52-29. In network mode, it is possible to transfer a word for every time slot, as shown in Figure 52-29. For more details, see Modes of Operation. In order to comply with AC-97 specifications, RSWS4-RSWS0 should be set to 0x00011 (20-bit slot, 20-bit word); RFSL and RFSR should be cleared, and RDC4-RDC0 should be set to 0x0C (13 words in frame).
7 RWA	ESAI_RCR Receiver Word Alignment Control. The Receiver Word Alignment Control (RWA) bit defines the alignment of the data word in relation to the slot. This is relevant for the cases where the word length is shorter than the slot length. If RWA is cleared, the data word is assumed to be left-aligned in the slot frame. If RWA is set, the data word is assumed to be right-aligned in the slot frame. If the data word is shorter than the slot length, the data bits which are not in the data word field are ignored. For data word lengths of less than 24 bits, the data word is right-extended with zeroes before being stored in the receive data registers.
6 RSHFD	ESAI_RCR Receiver Shift Direction. The RSHFD bit causes the receiver shift registers to shift data in MSB first when RSHFD is cleared or LSB first when RSHFD is set (see Figure 52-2 and Figure 52-3).
5–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 RE3	ESAI_RCR ESAI Receiver 3 Enable. When RE3 is set and TE2 is cleared, the ESAI receiver 3 is enabled and samples data at the SDO2/SDI3 pin. ESAI_TX2 and ESAI_RX3 should not be enabled at the same time (RE3=1 and TE2=1). When RE3 is cleared, receiver 3 is disabled by inhibiting data transfer into ESAI_RX3. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX3 data register. If RE3 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX3 will be invalid and must be discarded.
2 RE2	ESAI_RCR ESAI Receiver 2 Enable. When RE2 is set and TE3 is cleared, the ESAI receiver 2 is enabled and samples data at the SDO3/SDI2 pin. ESAI_TX3 and ESAI_RX2 should not be enabled at the same time (RE2=1 and TE3=1). When RE2 is cleared, receiver 2 is disabled by inhibiting data transfer into ESAI_RX2. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX2 data register. If RE2 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX2 will be invalid and must be discarded.

Table continues on the next page...

ESAI_RCR field descriptions (continued)

Field	Description
1 RE1	ESAI_RCR ESAI Receiver 1 Enable. When RE1 is set and TE4 is cleared, the ESAI receiver 1 is enabled and samples data at the SDO4/SDI1 pin. ESAI_TX4 and ESAI_RX1 should not be enabled at the same time (RE1=1 and TE4=1). When RE1 is cleared, receiver 1 is disabled by inhibiting data transfer into ESAI_RX1. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX1 data register. If RE1 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX1 will be invalid and must be discarded.
0 RE0	ESAI_RCR ESAI Receiver 0 Enable. When RE0 is set and TE5 is cleared, the ESAI receiver 0 is enabled and samples data at the SDO5/SDI0 pin. ESAI_TX5 and ESAI_RX0 should not be enabled at the same time (RE0=1 and TE5=1). When RE0 is cleared, receiver 0 is disabled by inhibiting data transfer into ESAI_RX0. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the ESAI_RX0 data register. If RE0 is set while some of the other receivers are already in operation, the first data word received in ESAI_RX0 will be invalid and must be discarded.

52.5.17 Receive Clock Control Register (ESAI_RCCR)

The read/write Receiver Clock Control Register (ESAI_RCCR) controls the ESAI receiver clock generator bit and frame sync rates, word length, and number of words per frame for the serial data. The ESAI_RCCR control bits are described in the following paragraphs.

NOTE

ARM Core clock is ipg_clk_esai in block ESAI which is from CCM's ahb_clk_root.

ESAI_RCCR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RHCKD	ESAI_RCCR Receiver High Frequency Clock Direction. The Receiver High Frequency Clock Direction (RHCKD) bit selects the source of the receiver high frequency clock when in the asynchronous mode (SYN=0) and the IF2/OF2 flag direction in the synchronous mode (SYN=1). In the asynchronous mode, when RHCKD is set, the internal clock generator becomes the source of the receiver high frequency clock and is the output on the HCKR pin. In the asynchronous mode, when RHCKD is cleared, the receiver high frequency clock source is external; the internal clock generator is disconnected from the HCKR pin, and an external clock source may drive this pin. When RHCKD is cleared, HCKR is an input; when RHCKD is set, HCKR is an output. In the synchronous mode when RHCKD is set, the HCKR pin becomes the OF2 output flag. If RHCKD is cleared, the HCKR pin becomes the IF2 input flag. Refer to Table 52-2 and Table 52-40.
22 RFSD	ESAI_RCCR Receiver Frame Sync Signal Direction. The Receiver Frame Sync Signal Direction (RFSD) bit selects the source of the receiver frame sync signal when in the asynchronous mode (SYN=0) and the IF1/OF1/Transmitter Buffer Enable flag direction in the synchronous mode (SYN=1). In the asynchronous mode, when RFSD is set, the internal clock generator becomes the source of the receiver frame sync and is the output on the FSR pin. In the asynchronous mode, when RFSD is cleared, the receiver frame sync source is external; the internal clock generator is disconnected from the FSR pin, and an external clock source may drive this pin. In the synchronous mode when RFSD is set, the FSR pin becomes the OF1 output flag or the Transmitter Buffer Enable, according to the TEBE control bit. If RFSD is cleared, the FSR pin becomes the IF1 input flag. Refer to Table 52-2 and Table 52-39 .
21 RCKD	ESAI_RCCR Receiver Clock Source Direction. The Receiver Clock Source Direction (RCKD) bit selects the source of the clock signal used to clock the receive shift register in the asynchronous mode (SYN=0) and the IF0/OF0 flag direction in the synchronous mode (SYN=1). In the asynchronous mode, when RCKD is set, the internal clock source becomes the bit clock for the receive shift registers and word length divider and is the output on the SCKR pin. In the asynchronous mode when RCKD is cleared, the clock source is external; the internal clock generator is disconnected from the SCKR pin, and an external clock source may drive this pin. In the synchronous mode when RCKD is set, the SCKR pin becomes the OF0 output flag. If RCKD is cleared, the SCKR pin becomes the IF0 input flag. Refer to Table 52-2 and Table 52-38.
20 RHCKP	ESAI_RCCR Receiver High Frequency Clock Polarity. The Receiver High Frequency Clock Polarity (RHCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If RHCKP is cleared the data and the frame sync are clocked out on the rising edge of the receive high frequency bit clock and the frame sync is latched in on the falling edge of the receive bit clock. If RHCKP is set the falling edge of the receive clock is used to clock the data and frame sync out and the rising edge of the receive clock is used to latch the frame sync in.
19 RFSP	ESAI_RCCR Receiver Frame Sync Polarity. The Receiver Frame Sync Polarity (RFSP) determines the polarity of the receive frame sync signal. When RFSP is cleared the frame sync signal polarity is positive, that is, the frame start is indicated by a high level on the frame sync pin. When RFSP is set the frame sync signal polarity is negative, that is, the frame start is indicated by a low level on the frame sync pin.
18 RCKP	The Receiver Clock Polarity (RCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If RCKP is cleared the data and the frame sync are clocked out on the rising edge of the receive bit clock and the frame sync is latched in on the falling edge of the receive bit clock. If RCKP is set the falling edge of the receive clock is used to clock the data and frame sync out and the rising edge of the receive clock is used to latch the frame sync in.
17–14 RFP[3:0]	ESAI_RCCR Rx High Frequency Clock Divider. The RFP3-RFP0 bits control the divide ratio of the receiver high frequency clock to the receiver serial bit clock when the source of the receiver high frequency clock and the bit clock is the internal Arm Core clock. When the HCKR input is being driven

Table continues on the next page...

ESAI_RCCR field descriptions (continued)

Field	Description
	from an external high frequency clock, the RFP3-RFP0 bits specify an additional division ration in the clock divider chain. Table 52-37 provides the specification of the divide ratio. Figure 52-32 shows the ESAI high frequency generator functional diagram.
13–9 RDC[4:0]	ESAI_RCCR Rx Frame Rate Divider Control. The RDC4-RDC0 bits control the divide ratio for the programmable frame rate dividers used to generate the receiver frame clocks. In network mode, this ratio may be interpreted as the number of words per frame minus one. The divide ratio may range from 2 to 32 (RDC[4:0]=0x00001 to 0x11111) for network mode. A divide ratio of one (RDC[4:0]=0x00000) in network mode is a special case (on-demand mode). In normal mode, this ratio determines the word transfer rate. The divide ratio may range from 1 to 32 (RDC[4:0]=0x00000 to 0x11111) for normal mode. In normal mode, a divide ratio of one (RDC[4:0]=0x00000) provides continuous periodic data word transfers. A bit-length frame sync (RFSL=1) must be used in this case. The ESAI frame sync generator functional diagram is shown in Figure 52-33 .
8 RPSR	ESAI_RCCR Receiver Prescaler Range. The RPSR controls a fixed divide-by-eight prescaler in series with the variable prescaler. This bit is used to extend the range of the prescaler for those cases where a slower bit clock is desired. When RPSR is set, the fixed prescaler is bypassed. When RPSR is cleared, the fixed divide-by-eight prescaler is operational (see Figure 52-32). The maximum internally generated bit clock frequency is Fsys/4, the minimum internally generated bit clock frequency is Fsys/(2 x 8 x 256 x 16)=Fsys/65536. (Do not use the combination RPSR=1 and RPM7-RPM0 =0x00, which causes synchronization problems when using the internal Core clock as source (RHCKD=1 or RCKD=1))
7–0 RPM[7:0]	ESAI_RCCR Receiver Prescale Modulus Select. The RPM7-RPM0 bits specify the divide ratio of the prescale divider in the ESAI receiver clock generator. A divide ratio from 1 to 256 (RPM[7:0]=0x00 to 0xFF) may be selected. The bit clock output is available at the receiver serial bit clock (SCKR) pin. The bit clock output is also available internally for use as the bit clock to shift the receive shift registers. The ESAI receive clock generator functional diagram is shown in Figure 52-32.

52.5.18 Transmit Slot Mask Register A (ESAI_TSMA)

The Transmit Slot Mask Register A together with Transmit Slot Mask Register B (ESAI_TSMA and ESAI_TSMB) are two read/write registers used by the transmitters in network mode to determine for each slot whether to transmit a data word and generate a transmitter empty condition (TDE=1), or to tri-state the transmitter data pins. Fields ESAI_TSMA [TS[15:0]] and ESAI_TSMB [TS[31:16]] are concatenated to form the 32-bit field TS[31:0]. Bit number n in TS[31:0] is the enable/disable control bit for transmission in slot number n.

Address: 4006_2000h base + E4h offset = 4006_20E4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ESAI_TSMA field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 TS[15:0]	When bit number N in ESAI_TSMA is cleared, all the transmit data pins of the enabled transmitters are tri-stated during transmit time slot number N. The data is still transferred from the transmit data registers to the transmit shift registers but neither the TDE nor the TUE flags are set. This means that during a disabled slot, no transmitter empty interrupt is generated. The Core is interrupted only for enabled slots. Data that is written to the transmit data registers when servicing this request is transmitted in the next enabled transmit time slot. When bit number N in ESAI_TSMA register is set, the transmit sequence is as usual: data is transferred from the TX registers to the shift registers and transmitted during slot number N, and the TDE flag is set. Using the slot mask in ESAI_TSMA does not conflict with using TSR. Even if a slot is enabled in ESAI_TSMA, the user may choose to write to TSR instead of writing to the transmit data registers TXn. This causes all the transmit data pins of the enabled transmitters to be tri-stated during the next slot. Data written to the ESAI_TSMA affects the next frame transmission. The frame being transmitted is not affected by this data and would comply to the last ESAI_TSMA setting. Data read from ESAI_TSMA returns the last written data. After hardware or software reset, the ESAI_TSMA register is preset to 0x0000FFFF, which means that all 16 possible slots are enabled for data transmission. When operating in normal mode, bit 0 of the ESAI_TSMA register must be set, otherwise no output is generated.

52.5.19 Transmit Slot Mask Register B (ESAI_TSMB)

The Transmit Slot Mask Register B together with Transmit Slot Mask Register A (ESAI_TSMA and ESAI_TSMB) are two read/write registers used by the transmitters in network mode to determine for each slot whether to transmit a data word and generate a transmitter empty condition (TDE=1), or to tri-state the transmitter data pins. Fields ESAI_TSMA [TS[15:0]] and ESAI_TSMB [TS[31:16]] are concatenated to form the 32-bit field TS[31:0]. Bit number n in TS[31:0] is the enable/disable control bit for transmission in slot number n.

Address: 4006_2000h base + E8h offset = 4006_20E8h

Chapter 53
Asynchronous Sample Rate Converter (ASRC)

53.1 Introduction

The figure below is a system view of the connection between the ASRC block and other blocks.

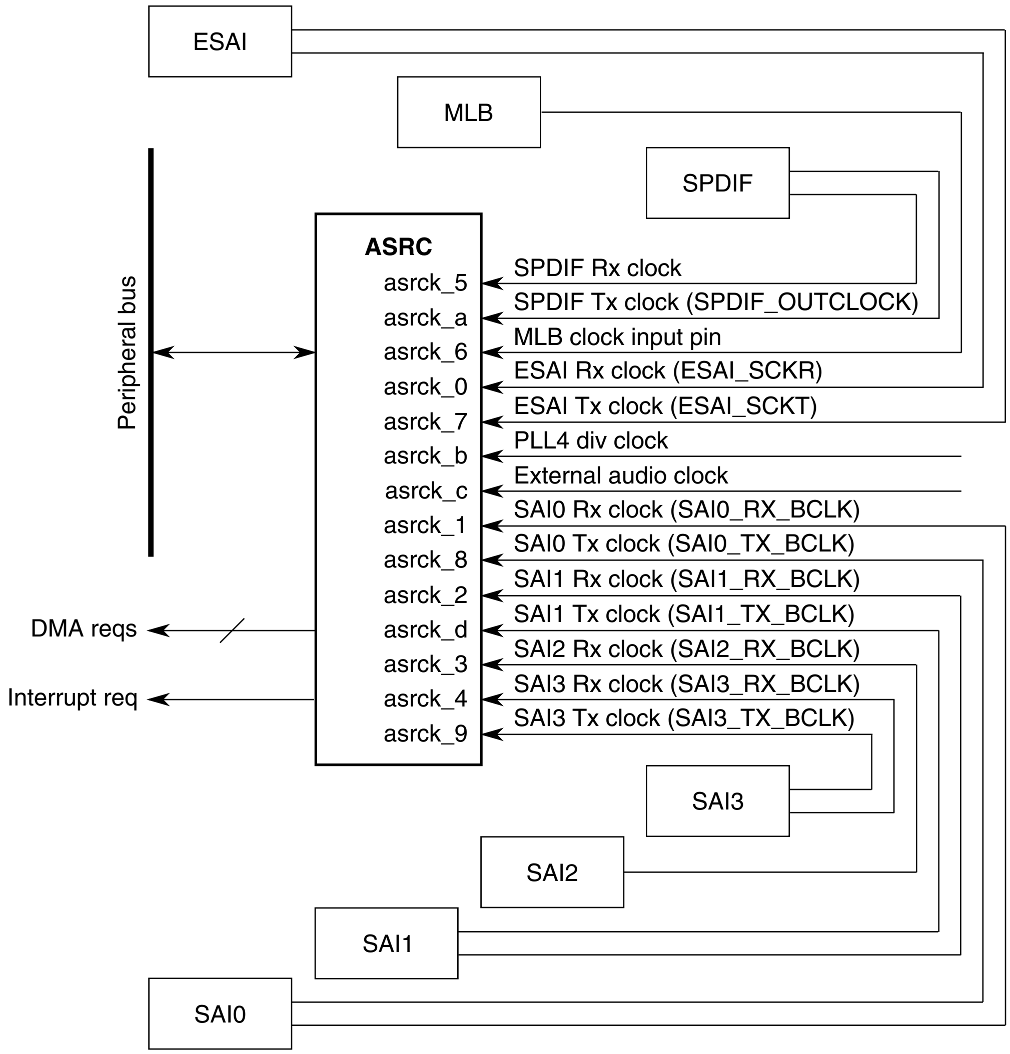

Figure 53-1. System Overview

The following figure is the ASRC block diagram.

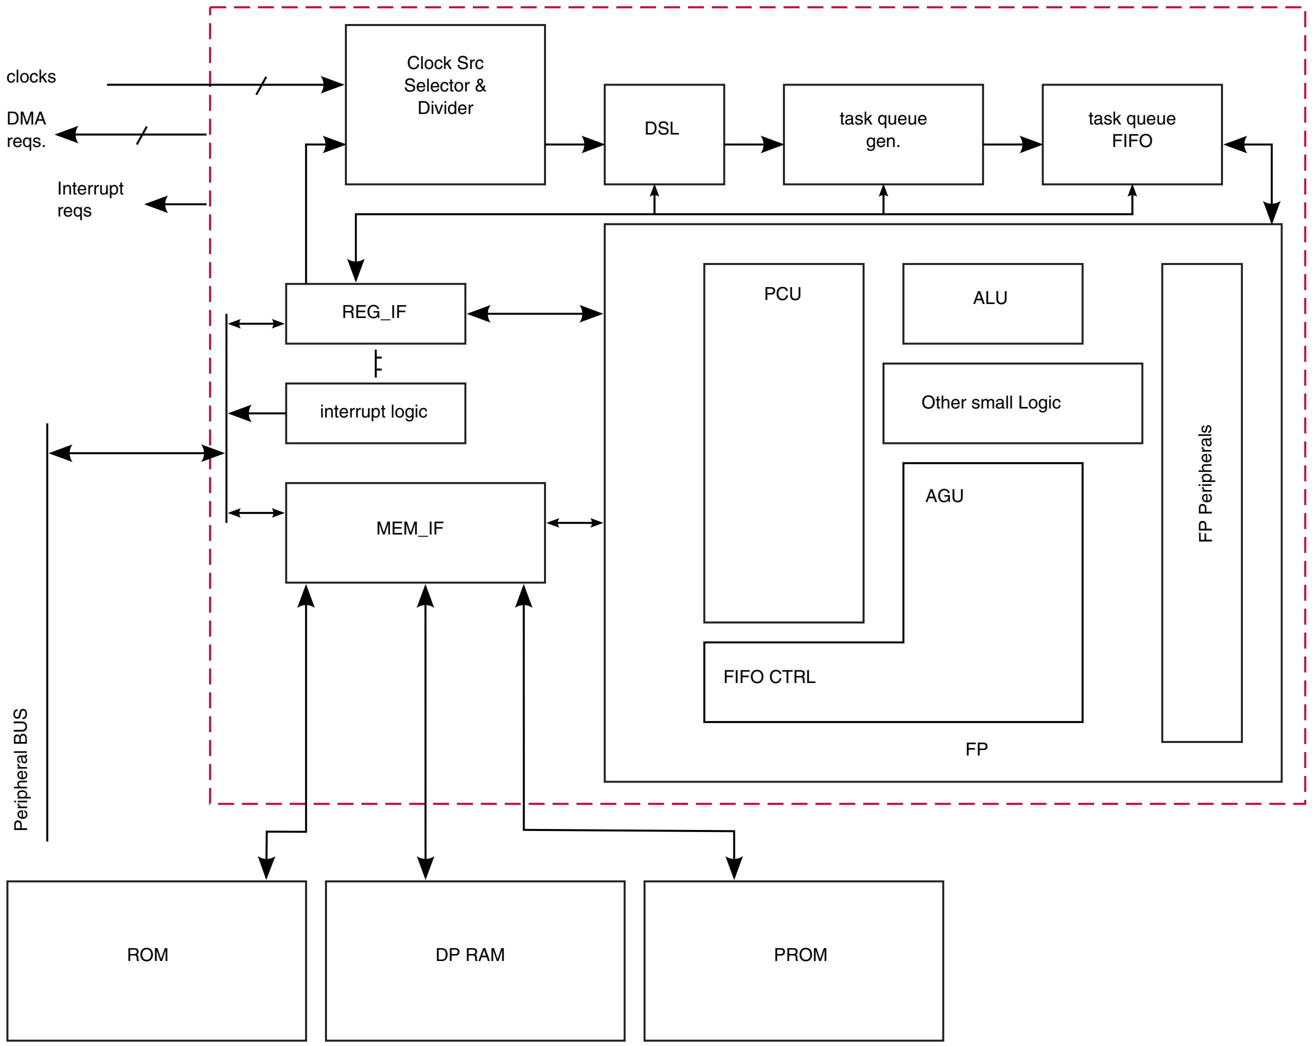

Figure 53-2. ASRC block diagram

53.1.1 Overview

The Asynchronous Sample Rate Converter (ASRC) converts the sampling rate of a signal associated with an input clock into a signal associated with a different output clock. The ASRC supports concurrent sample rate conversion of up to 10 channels of about -120dB THD+N. The ASRC supports up to three sampling rate pairs.

The incoming audio data to this chip may be received from various sources at different sampling rates. The outgoing audio data of this chip may have different sampling rates and it can also be associated with output clocks that are asynchronous to the input clocks.

The ASRC is implemented as a co-processor in hardware, with minimal ARM Platform intervention required.

53.1.2 Features

Features:

- Any number (0-10) of contiguous channels can be associated to one of the sampling rate pairs.
- Support user-programmable threshold for the input/output FIFOs.
- Support flexible 8/16/24 bit width of input data, and 16/24 bit width of output data.
- Designed for rate conversion between 44.1kHz, 32kHz, 48kHz, 96kHz, and 192kHz. The useful signal bandwidth is below 24kHz.
- Other input sampling rates in the range of 8kHz to 200kHz is also supported, but possibly with less desirable bandwidth.
- Other output sampling rates in the range of 30kHz to 200kHz is also supported, but possibly with less desirable bandwidth.
- Limited support for the case when output sampling rates is between 8kHz and 30kHz. The limitation is the supported ratio (Fsin/Fsout) range as between 1/24 to 8
- Automatic accommodation to slow variations in the incoming and outgoing sampling rates.
- Linear phase
- Tolerant to sample clock jitter
- Designed for real-time streaming audio usage. The output sampling clock must be always physically available in the system.

Clock/Data Connections

- The sampling rate clocks are directly connected to the ASRC block, the ratio estimation of the input clocks with output clocks are done in ASRC hardware.
- The clock signals come from the following blocks, for example:
  - ESAI, receiving bit clock and transmitting bit clock
  - SAI, receiving bit clock and transmitting bit clock
  - SPDIF, receiving bit clock and transmitting bit clock
  - other audio peripherals etc.
- The exchange of audio data is done by the processor accessing ASRC block through registers defined on shared peripheral bus.

53.1.3 Modes of Operation

See the Programmable Registers section for a definition of the registers and parameters used in ASRC.

53.1.3.1 Data Transfer Schemes

53.1.3.1.1 Data Input Modes

The input mode for each of the three channel sets may be set independently. Three modes of supplying data to the ASRC input FIFOs are available:

- Polling
- Interrupt
- DMA

In all input-data transfer schemes, the ASRC fetches data from each enabled FIFO and processes the data sample-by-sample after each rising edge of the associated input sampling clock until the FIFO level reaches a threshold.

After the threshold is reached, the ASRC requests data. The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples. The threshold can be defined by interface registers ASRMCRx, x=A, B or C.

If the ASRC attempts to fetch data from an empty FIFO, an error is generated and the ASRSTR_AOLE bit is set. If the ASRC overload interrupt is enabled (ASRIER_AOLIE bit is set), an interrupt is generated.

When writing data to an input FIFO, you must ensure that it is in a predefined sequence. For example, when writing to an input FIFO, the sequence should be: channel_0, channel_1, channel_2,..., channel_n, channel_0, channel_1, channel_2, etc. Here channel_n stands for the data intended for the n-th channel. The hardware will re-allocate each data to its corresponding channel FIFO. The channel being re-allocated is shown by ASRCCR_ACIA.

Mode 1 (Polling Mode)

Polling mode is the default mode following power-on or individual reset, and is selected by clearing the associated channel set A, B, or C data-input interrupt enable bit (ASRIER_ADIEx, where x=A, B or C). In this mode, data-input interrupts are disabled. When the FIFO level is below the threshold, the associated status bit (ASRSTR_AIDEx, where x=A, B, or C) is set. To clear the status bit, the FIFO must be written with enough data to raise the level above the threshold.

Mode 2 (Interrupt Mode)

The ASRC input FIFOs can also be serviced by interrupts. To enable interrupts, the corresponding data-input interrupt enable bits (ASRIER_ADIEx, where x=A, B, or C) should be set. An interrupt is automatically generated any time the input FIFO level is below the threshold. The interrupt is cleared when enough data is written to the FIFO to raise the level above the threshold.

Mode 3 (DMA Mode)

The ASRC input FIFOs can also be filled using DMA. In this mode, the data-input interrupt-enable bits (ASRIER_ADIEx, where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

53.1.3.1.2 Data Output Modes

The output mode for each of the 3 channel sets (A, B, and C) may be set independently.

Three modes of retrieving data from the ASRC output FIFOs are available:

- Polling
- Interrupt
- DMA

In all output-data transfer schemes, the ASRC places a processed sample into the associated output FIFO. After a threshold is reached, the ASRC requests that data be transferred out of the FIFO.

The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples. The threshold can be defined by interface registers ASRMCRx, x=A, B or C.

If the ASRC attempts to place data into a FIFO that is already full, an error is generated and the ASRSTR_AOLE bit is set. If the ASRC overload interrupt is enabled (ASRIER_AOLIE bit is set), an interrupt is generated.

Each output FIFO is organized in the same channel order in which the associated input FIFO was written.

Two transfer modes are supported by Interface Block.

Mode 1 (Polling Mode)

The ASRC output FIFOs can be serviced by polling. In this mode, ensure the associated output-data interrupt enable bit (ASRIER_ADOEx, where x=A, B, or C) is cleared. In this mode, all output-data interrupts are disabled. Any time the output FIFO exceeds the threshold the associated status bit (ASRSTR_AODFx, where x=A, B, or C) is set. To clear the status bit, enough data must be read from the associated output FIFO to lower the level below the threshold.

Mode 2 (Interrupt Mode)

The ASRC output FIFOs may also be serviced using interrupts. To enable this mode, the corresponding output-data interrupt-enable bits (ASRIER_ADOEx, where x=A, B, or C) should be set. Any time the output FIFO level exceeds the threshold, an interrupt is automatically generated. The interrupt is cleared when enough data is read from the FIFO to lower the level below the threshold.

Mode 3 (DMA Mode)

The ASRC output FIFOs can also be read using DMA. In this mode, the output-data interrupt-enable bits (ASRIER_ADOEx, where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

53.1.3.2 Word Alignment Supported

53.1.3.2.1 Input Data Alignment Modes

The position and length of input data word to the input data FIFOs ASRDIA, ASRDIB, ASRDIC are programmable. The control bits are defined in ASRMCR1x {x=A, B, or C}. It supports the following modes.

Table 53-1. Input Data Alignment

Format	Bit Number																														
	31	**30**	**29**	**28**	**27**	**26**	**25**	**24**	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**

53.2 Interrupts

ASRC has several interrupts events.

Priority	Description
lowest	ASRC Pair A input data needed
	ASRC Pair B input data needed
	ASRC Pair C input data needed
	ASRC Pair A output data ready
	ASRC Pair B output data ready
	ASRC Pair C output data ready
	ASRC Overload

53.3 DMA requests

ASRC has six DMA requests. They are directly connected to the lowest six status bits in the ASRSTR register.

Table 53-4. DMA requests

Type	Description
0	ASRC Pair A input data needed
1	ASRC Pair B input data needed
2	ASRC Pair C input data needed
3	ASRC Pair A output data ready
4	ASRC Pair B output data ready
5	ASRC Pair C output data ready

53.4 Programmable Registers

All useful registers are listed in the memory map below. The access of undefined registers will behave as normal registers.

All the interface registers are LSB aligned except the input FIFOs and the output FIFOs, and each register has only 24 effective bits.

The input FIFO and output FIFO word alignment can be defined using ASRMCR1{A,B,C} registers in 32-bit interface system.

ASRC_ASRCTR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 -	This field is reserved. Reserved. Should be written as zero for compatibility.
22 ATSC	ASRC Pair C Automatic Selection For Processing Options When this bit is 1, pair C will automatic update its pre-processing and post-processing options (ASRCFG: PREMODC, ASRCFG:POSTMODC) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly. When this bit is 0, the user needs to choose the proper processing options for pair C. This bit should be disabled when {USRC, IDRC}={1,1}.
21 ATSB	ASRC Pair B Automatic Selection For Processing Options When this bit is 1, pair B will automatic update its pre-processing and post-processing options (ASRCFG: PREMODB, ASRCFG:POSTMODB) based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly. When this bit is 0, the user is responsible for choosing the proper processing options for pair B. This bit should be disabled when {USRB, IDRB}={1,1}.
20 ATSA	ASRC Pair A Automatic Selection For Processing Options When this bit is 1, pair A will automatic update its pre-processing and post-processing options (ASRCFG: PREMODA, ASRCFG:POSTMODA)based on the frequencies it detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly. When this bit is 0, the user needs to choose the proper processing options for pair A. This bit should be disabled when {USRA, IDRA}={1,1}.
19 -	This field is reserved. Reserved. Should be written as zero for compatibility.
18 USRC	Use Ratio for Pair C Use ratio as the input to ASRC. This bit is used in conjunction with IDRC control bit.
17 IDRC	Use Ideal Ratio for Pair C When USRC=0, this bit has no usage. When USRC=1 and IDRC=0, ASRC internal measured ratio will be used. When USRC=1 and IDRC=1, the idea ratio from the interface register ASRIDRHC, ASRIDRLC will be used. It is suggested to manually set ASRCFG:POSTMODC, ASRCFG:PREMODC.
16 USRB	Use Ratio for Pair B Use ratio as the input to ASRC. This bit is used in conjunction with IDRB control bit.
15 IDRB	Use Ideal Ratio for Pair B When USRB=0, this bit has no usage. When USRB=1 and IDRB=0, ASRC internal measured ratio will be used. When USRB=1 and IDRB=1, the idea ratio from the interface register ASRIDRHB, ASRIDRLB will be used.It is suggested to manually set ASRCFG:POSTMODB, ASRCFG:PREMODB.
14 USRA	Use Ratio for Pair A Use ratio as the input to ASRC. This bit is used in conjunction with IDRA control bit.

Table continues on the next page...

ASRC_ASRCTR field descriptions (continued)

Field	Description
13 IDRA	Use Ideal Ratio for Pair A When USRA=0, this bit has no usage. When USRA=1 and IDRA=0, ASRC internal measured ratio will be used. When USRA=1 and IDRA=1, the idea ratio from the interface register ASRIDRHA, ASRIDRLA will be used. It is suggested to manually set ASRCFG:POSTMODA, ASRCFG:PREMODA.
12–5 -	This field is reserved. Reserved. Should be written as zero for compatibility.
4 SRST	Software Reset This bit is self-clear bit. Once it is been written as 1, it will generate a software reset signal inside ASRC. After 9 cycles of the ASRC processing clock, this reset process will stop, and this bit will be cleared automatically.
3 ASREC	ASRC Enable C Enable the operation of the conversion C of ASRC. When ASREC is cleared, operation of conversion C is disabled.
2 ASREB	ASRC Enable B Enable the operation of the conversion B of ASRC. When ASREB is cleared, operation of conversion B is disabled.
1 ASREA	ASRC Enable A Enable the operation of the conversion A of ASRC. When ASREA is cleared, operation of conversion A is disabled.
0 ASRCEN	ASRC Enable Enable the operation of ASRC.

53.4.2 ASRC Interrupt Enable Register (ASRC_ASRIER)

Address: 4006_0000h base + 4h offset = 4006_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ASRC_ASRIER field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–8 -	This field is reserved. Reserved. Should be written as zero for compatibility.
7 AFPWE	FP in Wait State Interrupt Enable Enables the FP in wait state interrupt. 1 interrupt enabled 0 interrupt disabled
6 AOLIE	Overload Interrupt Enable Enables the overload interrupt. 1 interrupt enabled 0 interrupt disabled
5 ADOEC	Data Output C Interrupt Enable Enables the data output C interrupt. 1 interrupt enabled 0 interrupt disabled
4 ADOEB	Data Output B Interrupt Enable Enables the data output B interrupt. 1 interrupt enabled 0 interrupt disabled
3 ADOEA	Data Output A Interrupt Enable Enables the data output A interrupt. 1 interrupt enabled 0 interrupt disabled
2 ADIEC	Data Input C Interrupt Enable Enables the data input C interrupt. 1 interrupt enabled 0 interrupt disabled
1 ADIEB	Data Input B Interrupt Enable Enables the data input B interrupt. 1 interrupt enabled 0 interrupt disabled
0 ADIEA	Data Input A Interrupt Enable Enables the data input A Interrupt. 1 interrupt enabled 0 interrupt disabled

53.4.3 ASRC Channel Number Configuration Register (ASRC_ASRCNCR)

The ASRC channel number configuration register (ASRCNCR) is a 24-bit read/write register that sets the number of channels used by each ASRC conversion pair.

There are 10 channels available for distribution among 3 conversion pairs, they are ordered as 0,1,...,9. The bottom [0, ANCA-1] channels are used for pair A, the top [10-ANCC, 9] channels are used for pair C, and the [ANCA, ANCA+ANCB-1] channels are allocated for pair B. In case that ANCA=0, then the [0, ANCB-1] channels are assigned for pair B.

Address: 4006_0000h base + Ch offset = 4006_000Ch

Bit	31–24	23–12	11–8	7–4	3–0

23–12 -	This field is reserved. Reserved. Should be written as zero for compatibility.
11–9 AOCDC	Output Clock Divider C Specify the divide ratio of the output clock divider C. The divide ratio may range from 1 to 8 (AOCDC[2:0] = 000 to 111).
8–6 AOCPC	Output Clock Prescaler C Specify the prescaling factor of the output prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.
5–3 AICDC	Input Clock Divider C Specify the divide ratio of the input clock divider C. The divide ratio may range from 1 to 8 (AICDC[2:0] = 000 to 111).
2–0 AICPC	Input Clock Prescaler C Specify the prescaling factor of the input prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.

53.4.8 ASRC Status Register (ASRC_ASRSTR)

The ASRC status register (ASRSTR) is a 24-bit read-write register used by the processor core to examine the status of the ASRC block and clear the overload interrupt request and AOLE flag bit. Read the status register will return the current state of ASRC.

Address: 4006_0000h base + 20h offset = 4006_0020h

ASRC_ASRSTR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.

Table continues on the next page...

ASRC_ASRSTR field descriptions (continued)

Field	Description
23–22 -	This field is reserved. Reserved. Should be written as zero for compatibility.
21 DSLCNT	DSL Counter Input to FIFO ready When set, this bit indicates that new DSL counter information is stored in the internal ASRC FIFO. When clear, this bit indicates that new DSL counter information is in the process of storage into the internal ASRC FIFO. When ASRIER:AFPWE=1, the rising edge of this signal will propose an interrupt request. Writing any value with this bit set will clear the interrupt request proposed by the rising edge of this bit.
20 ATQOL	Task Queue FIFO overload When set, this bit indicates that task queue FIFO logic is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
19 AOOLC	Pair C Output Task Overload When set, this bit indicates that pair C output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
18 AOOLB	Pair B Output Task Overload When set, this bit indicates that pair B output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
17 AOOLA	Pair A Output Task Overload When set, this bit indicates that pair A output task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
16 AIOLC	Pair C Input Task Overload When set, this bit indicates that pair C input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
15 AIOLB	Pair B Input Task Overload When set, this bit indicates that pair B input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
14 AIOLA	Pair A Input Task Overload When set, this bit indicates that pair A input task is oveloaded. This may help to check the reason why overload interrupt happens. The bit is cleared when writing ASRCTR:AOLIE as 1.
13 AODOC	Output Data Buffer C has overflowed When set, this bit indicates that output data buffer C has overflowed. When clear, this bit indicates that output data buffer C has not overflowed
12 AODOB	Output Data Buffer B has overflowed When set, this bit indicates that output data buffer B has overflowed. When clear, this bit indicates that output data buffer B has not overflowed

Table continues on the next page...

ASRC_ASRSTR field descriptions (continued)

Field	Description
11 AODOA	Output Data Buffer A has overflowed When set, this bit indicates that output data buffer A has overflowed. When clear, this bit indicates that output data buffer A has not overflowed
10 AIDUC	Input Data Buffer C has underflowed When set, this bit indicates that input data buffer C has underflowed. When clear, this bit indicates that input data buffer C has not underflowed.
9 AIDUB	Input Data Buffer B has underflowed When set, this bit indicates that input data buffer B has underflowed. When clear, this bit indicates that input data buffer B has not underflowed.
8 AIDUA	Input Data Buffer A has underflowed When set, this bit indicates that input data buffer A has underflowed. When clear, this bit indicates that input data buffer A has not underflowed.
7 FPWT	FP is in wait states This bit is for debug only. When set, this bit indicates that ASRC is in wait states. When clear, this bit indicates that ASRC is not in wait states. If ASRCTR:AFPWE=1 and ASRCTR:ASDBG=1, an interrupt will be proposed when this bit is set.
6 AOLE	Overload Error Flag When set, this bit indicates that the task rate is too high for the ASRC to handle. The reasons for overload may be: - too high input clock frequency, - too high output clock frequency, - incorrect selection of the pre-filter, - low ASRC processing clock, - too many channels, - underrun, - or any combination of the reasons above. Since the ASRC uses the same hardware resources to perform various tasks, the real reason for the overload is not straight forward, and it should be carefully analyzed by the programmer. If ASRCTR:AOLIE=1, an interrupt will be proposed when this bit is set. Write any value with this bit set as one into the status register will clear this bit and the interrupt request proposed by this bit.
5 AODFC	Number of data in Output Data Buffer C is greater than threshold When set, this bit indicates that number of data already existing in ASRDORC is greater than threshold and the processor can read data from ASRDORC. When AODFC is set, the ASRC generates data output C interrupt request to the processor, if enabled (that is, ASRCTR:ADOEC = 1). A DMA request is always generated when the AODFC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
4 AODFB	Number of data in Output Data Buffer B is greater than threshold

Table continues on the next page...

ASRC_ASRSTR field descriptions (continued)

Field	Description
	When set, this bit indicates that number of data already existing in ASRDORB is greater than threshold and the processor can read data from ASRDORB. When AODFB is set, the ASRC generates data output B interrupt request to the processor, if enabled (that is, ASRCTR:ADOEB = 1). A DMA request is always generated when the AODFB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
3 AODFA	Number of data in Output Data Buffer A is greater than threshold When set, this bit indicates that number of data already existing in ASRDORA is greater than threshold and the processor can read data from ASRDORA. When AODFA is set, the ASRC generates data output A interrupt request to the processor, if enabled (that is, ASRCTR:ADOEA = 1). A DMA request is always generated when the AODFA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
2 AIDEC	Number of data in Input Data Buffer C is less than threshold When set, this bit indicates that number of data still available in ASRDIRC is less than threshold and the processor can write data to ASRDIRC. When AIDEC is set, the ASRC generates data input C interrupt request to the processor, if enabled (that is, ASRCTR:ADIEC = 1). A DMA request is always generated when the AIDEC bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
1 AIDEB	Number of data in Input Data Buffer B is less than threshold When set, this bit indicates that number of data still available in ASRDIRB is less than threshold and the processor can write data to ASRDIRB. When AIDEB is set, the ASRC generates data input B interrupt request to the processor, if enabled (that is, ASRCTR:ADIEB = 1). A DMA request is always generated when the AIDEB bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.
0 AIDEA	Number of data in Input Data Buffer A is less than threshold When set, this bit indicates that number of data still available in ASRDIRA is less than threshold and the processor can write data to ASRDIRA. When AIDEA is set, the ASRC generates data input A interrupt request to the processor, if enabled (that is, ASRCTR:ADIEA = 1). A DMA request is always generated when the AIDEA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.

53.4.9 ASRC Parameter Register n (ASRC_ASRPMn*n*)

Parameter registers determine the performance of ASRC.

The parameter registers must be initialized by software before ASRC is enabled.

Table 53-16. ASRC Parameter Registers (ASRPM1~ASRPM5)

Register	Offset	Access	Reset Value	Recommend Value
asrcpm1	0x40	R/W	0x00_0000	0x7fffff

23–0 DATA	Audio data input

53.4.13 ASRC Data Output Register for Pair *x* (ASRC_ASRDO*n*)

These registers are the interface registers for the audio data output of pair A,B,C respectively. They are backed by FIFOs.

Address: 4006_0000h base + 64h offset + (8d × i), where i=0d to 2d

Bit	31–24	23–0
R	Reserved	DATA
W		
Reset	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

ASRC_ASRDO*n* field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–0 DATA	Audio data output

53.4.14 ASRC Ideal Ratio for Pair A-High Part (ASRC_ASRIDRHA)

The ideal ratio registers (ASRIDRHA, ASRIDRLA) hold the ratio value IDRATIOA. IDRATIOA = Fs $_{inA}$ /Fs $_{outA}$ = Ts $_{outA}$ /Ts $_{inA}$ is a 32-bit fixed point value with 26 fractional bits. This value is only useful when ASRCTR:{USRA, IDRA}=2'b11.

Address: 4006_0000h base + 80h offset = 4006_0080h

Bit	31–24	23–16	15–8	7–0
R/W	Reserved	Reserved	Reserved	IDRATIOA[31:24]

23–0 IDRATIOC[23:0]	IDRATIOC[23:0]. Low part of ideal ratio value for pair C.

53.4.20 ASRC 76kHz Period in terms of ASRC processing clock (ASRC_ASR76K)

The register (ASR76K) holds the period of the 76kHz sampling clock in terms of the ASRC processing clock with frequency Fs_{ASRC} . ASR76K = Fs_{ASRC} /Fs_{76k} . Reset value is 0x0A47 which assumes that Fs_{ASRC} =200MHz. This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically. In a system when Fs_{ASRC} =133MHz, the value should be assigned explicitly as 0x06D6 in user application code.

Address: 4006_0000h base + 98h offset = 4006_0098h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ASRC_ASRMCRA field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 ZEROBUFA	Initialize buf of Pair A when pair A is enabled. Always clear option. This bit is used to control whether the buffer is to be zeroized when pair A is enabled. 1 Don't zeroize the buffer 0 Zeroize the buffer
22 EXTTHRSHA	Use external thresholds for FIFO control of Pair A This bit will determine whether the FIFO thresholds externally defined in this register is used to control ASRC internal FIFO logic for pair A. 1 Use external defined thresholds. 0 Use default thresholds.
21 BUFSTALLA	Stall Pair A conversion in case of Buffer Near Empty/Full Condition This bit will determine whether the near empty/full FIFO condition will stall the rate conversion for pair A. This option can only work when external ratio is used. Near empty condition is the condition when input FIFO has less than 4 useful samples per channel. Near full condition is the condition when the output FIFO has less than 4 vacant sample words to fill per channel.

Table continues on the next page...

ASRC_ASRMCRA field descriptions (continued)

Field	Description
	1 Stall Pair A conversion in case of near empty/full FIFO conditions. 0 Don't stall Pair A conversion even in case of near empty/full FIFO conditions.
20 BYPASSPOLYA	Bypass Polyphase Filtering for Pair A This bit will determine whether the polyphase filtering part of Pair A conversion will be bypassed. 1 Bypass polyphase filtering. 0 Don't bypass polyphase filtering.
19–18 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
17–12 OUTFIFO_ THRESHOLDA[5:0]	The threshold for Pair A's output FIFO per channel These bits stand for the threshold for Pair A's output FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of output FIFO fillings of the pair is greater than n samples per channel, the output data ready flag is set; when the number of output FIFO fillings of the pair is less than or equal to n samples per channel, the output data ready flag is automatically cleared.
11 RSYNIFA	Re-sync Input FIFO Channel Counter If bit set, force ASRCCR:ACIA=0. If bit clear, untouch ASRCCR:ACIA.
10 RSYNOFA	Re-sync Output FIFO Channel Counter If bit set, force ASRCCR:ACOA=0. If bit clear, untouch ASRCCR:ACOA.
9–6 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
5–0 INFIFO_ THRESHOLDA[5:0]	The threshold for Pair A's input FIFO per channel These bits stand for the threshold for Pair A's input FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of input FIFO fillings of the pair is less than n samples per channel, the input data needed flag is set; when the number of input FIFO fillings of the pair is greater than or equal to n samples per channel, the input data needed flag is automatically cleared. **NOTE:** This field is writable only if EXTHRSHA is set.

53.4.23 ASRC FIFO Status Register for Pair A (ASRC_ASRFSTA)

The register (ASRFSTA) is used to show Pair A internal FIFO conditions.

Address: 4006_0000h base + A4h offset = 4006_00A4h

23 ZEROBUFC	Initialize buf of Pair C when pair C is enabled This bit is used to control whether the buffer is to be zeroized when pair C is enabled. 1 Don't zeroize the buffer 0 Zeroize the buffer
22 EXTTHRSHC	Use external thresholds for FIFO control of Pair C

Table continues on the next page...

ASRC_ASRMCRC field descriptions (continued)

Field	Description
	This bit will determine whether the FIFO thresholds externally defined in this register is used to control ASRC internal FIFO logic for pair C. 1 Use external defined thresholds. 0 Use default thresholds.
21 BUFSTALLC	Stall Pair C conversion in case of Buffer Near Empty/Full Condition This bit will determine whether the near empty/full FIFO condition will stall the rate conversion for pair C. This option can only work when external ratio is used. Near empty condition is the condition when input FIFO has less than 4 useful samples per channel. Near full condition is the condition when the output FIFO has less than 4 vacant sample words to fill per channel. 1 Stall Pair C conversion in case of near empty/full FIFO conditions. 0 Don't stall Pair C conversion even in case of near empty/full FIFO conditions.
20 BYPASSPOLYC	Bypass Polyphase Filtering for Pair C This bit will determine whether the polyphase filtering part of Pair C conversion will be bypassed. 1 Bypass polyphase filtering. 0 Don't bypass polyphase filtering.
19–18 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
17–12 OUTFIFO_ THRESHOLDC[5:0]	The threshold for Pair C's output FIFO per channel These bits stand for the threshold for Pair C's output FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of output FIFO fillings of the pair is greater than n samples per channel, the output data ready flag is set; when the number of output FIFO fillings of the pair is less than or equal to n samples per channel, the output data ready flag is automatically cleared.
11 RSYNIFC	Re-sync Input FIFO Channel Counter If bit set, force ASRCCR:ACIC=0. If bit clear, untouch ASRCCR:ACIC.
10 RSYNOFC	Re-sync Output FIFO Channel Counter If bit set, force ASRCCR:ACOC=0. If bit clear, untouch ASRCCR:ACOC.
9–6 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
5–0 INFIFO_ THRESHOLDC[5:0]	The threshold for Pair C's input FIFO per channel These bits stand for the threshold for Pair C's input FIFO per channel. Possible range is [0,63]. When the value is n, it means that: when the number of input FIFO fillings of the pair is less than n samples per channel, the input data needed flag is set; when the number of input FIFO fillings of the pair is greater than or equal to n samples per channel, the input data needed flag is automatically cleared. **NOTE:** This field is writable only if EXTHRSHC is set.

53.4.27 ASRC FIFO Status Register for Pair C (ASRC_ASRFSTC)

The register (ASRFSTC) is used to show Pair C internal FIFO conditions.

Address: 4006_0000h base + B4h offset = 4006_00B4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								OAFC	Reserved				OUTFIFO_FILLC[5:0]		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	OUTFIFO_FILLC[5:0]				IAEC	Reserved				INFIFO_FILLC[5:0]						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ASRC_ASRFSTC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 OAFC	Output FIFO is near Full for Pair C This bit is to indicate whether the output FIFO of Pair C is near full.
22–19 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
18–12 OUTFIFO_ FILLC[5:0]	The fillings for Pair C's output FIFO per channel These bits stand for the fillings for Pair C's output FIFO per channel. Possible range is [0,64].

Table continues on the next page...

ASRC_ASRFSTC field descriptions (continued)

Field	Description
11 IAEC	Input FIFO is near Empty for Pair C This bit is to indicate whether the input FIFO of Pair C is near empty.
10–7 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
6–0 INFIFO_FILLC[5:0]	The fillings for Pair C's input FIFO per channel These bits stand for the fillings for Pair C's input FIFO per channel. Possible range is [0,64].

53.4.28 ASRC Misc Control Register 1 for Pair X (ASRC_ASRMCR1*n*)

The register (ASRMCR1A) is used to control Pair *x* internal logic (for data alignment etc.).

The bit assignment for all the input data formats is the same as that supported by the SSI.

Address: 4006_0000h base + C0h offset + (4d × i), where i=0d to 2d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved								Reserved							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved				IWD[2:0]			IMSB	Reserved					OMSB	OSGN	OW16
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ASRC_ASRMCR1*n* field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–12 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
11–9 IWD[2:0]	Data Width of the input FIFO These three bits will determine the bitwidth for the audio data into ASRC All other settings not shown are reserved. 3'b000 24-bit audio data. 3'b001 16-bit audio data.

Table continues on the next page...

ASRC_ASRMCR1*n* field descriptions (continued)

Field	Description
	3'b010 8-bit audio data.
8 IMSB	Data Alignment of the input FIFO This bit will determine the data alignment of the input FIFO. 1 MSB aligned. 0 LSB aligned.
7–3 -	This field is reserved. Reserved. Should be written as zero for future compatibility.
2 OMSB	Data Alignment of the output FIFO This bit will determine the data alignment of the output FIFO. 1 MSB aligned. 0 LSB aligned.
1 OSGN	Sign Extension Option of the output FIFO This bit will determine the sign extension option of the output FIFO. 1 Sign extension. 0 No sign extension.
0 OW16	Bit Width Option of the output FIFO This bit will determine the bit width option of the output FIFO. 1 16-bit output data 0 24-bit output data.

53.5 Functional Description

53.5.1 Algorithm Description

53.5.1.1 Signal Processing Flow

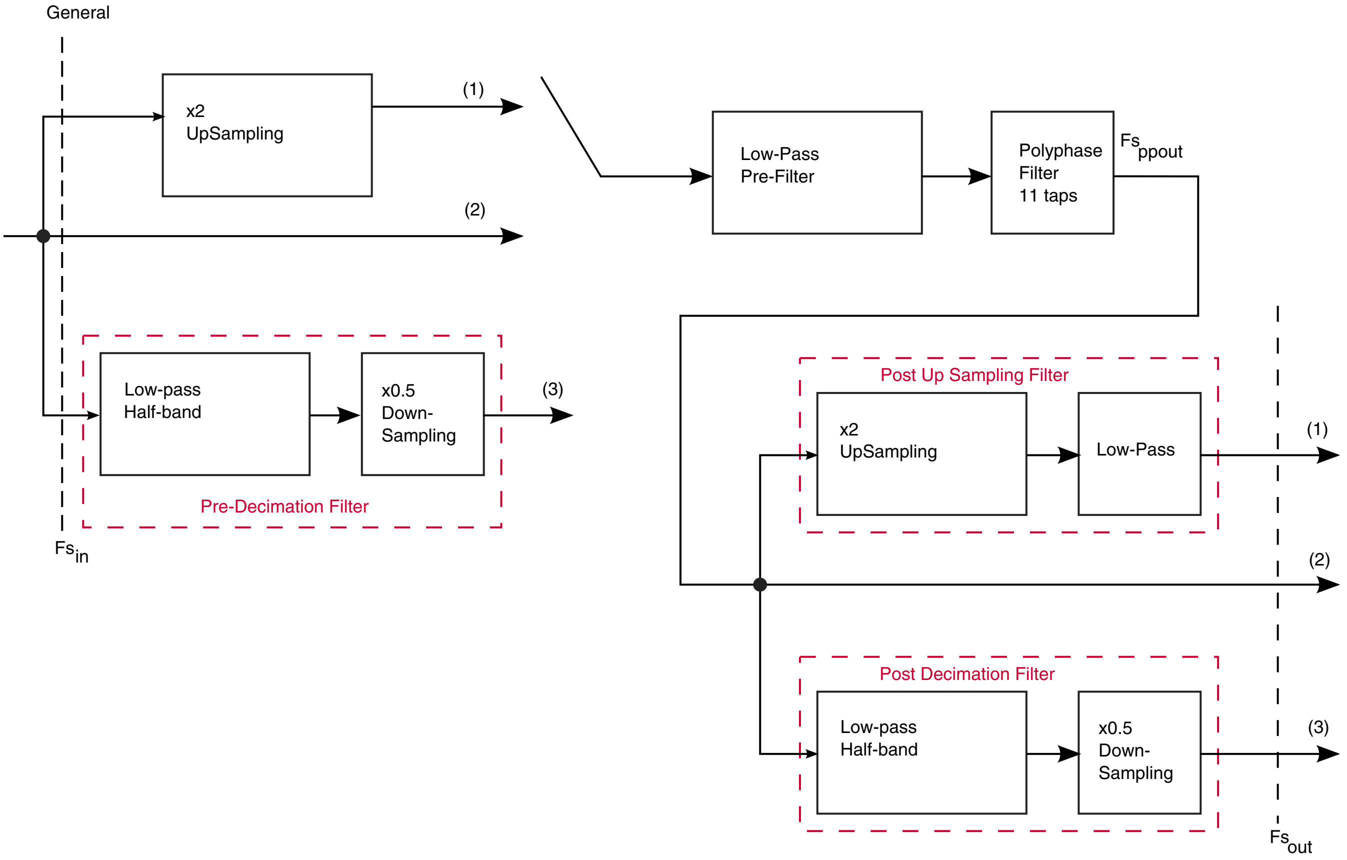

Figure 53-45. Signal processing configurations

The figure above shows the possible configurations of the ASRC. Each configuration consists of 2 to 4 stages.

- x2 up-sampling rate expander (zero insertion only) (Input Branch 1), or direct connection (Input Branch 2), or low-pass pre decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (Input Branch 3),
- low-pass pre-filter, the low-pass bandwidth is at most 0.25 x Fs, where Fs is the sampling rate of the input signal to this low-pass pre-filter,
- polyphase filter,
- x2 post upsampling filter (consisting of a x2 up-sampling rate expander (zero insertion only) with low-pass half-band FIR filter) (Output Branch 1), or direct connection (Output Branch 2), or low-pass post decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (Output Branch 3).

By flowing through different processing branches, and different setup of the pre-filter, this ASRC scheme can be used to handle different requirement of rate conversion.

Configuration (a): Input Branch 1+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (b): Input Branch 1+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (c): Input Branch 1+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

Configuration (d): Input Branch 2+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (e): Input Branch 2+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (f): Input Branch 2+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

Configuration (g): Input Branch 3+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (h): Input Branch 3+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (i): Input Branch 3+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$. The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

Table 53-55. Pre-Processing, Post-Processing Options

{Pre_Proc, Post_Proc}	Fsout (KHz)								
	8	32	44.1	48	64	88.2	96	128	192

Comments:

In the {Pre_Proc, Post_Proc} pair, the meaning of the values are:

Pre_Proc:

- 0 --- Pre-processing Branch 1
- 1 --- Pre-processing Branch 2
- 2 --- Pre-processing Branch 3 decimation-by-2

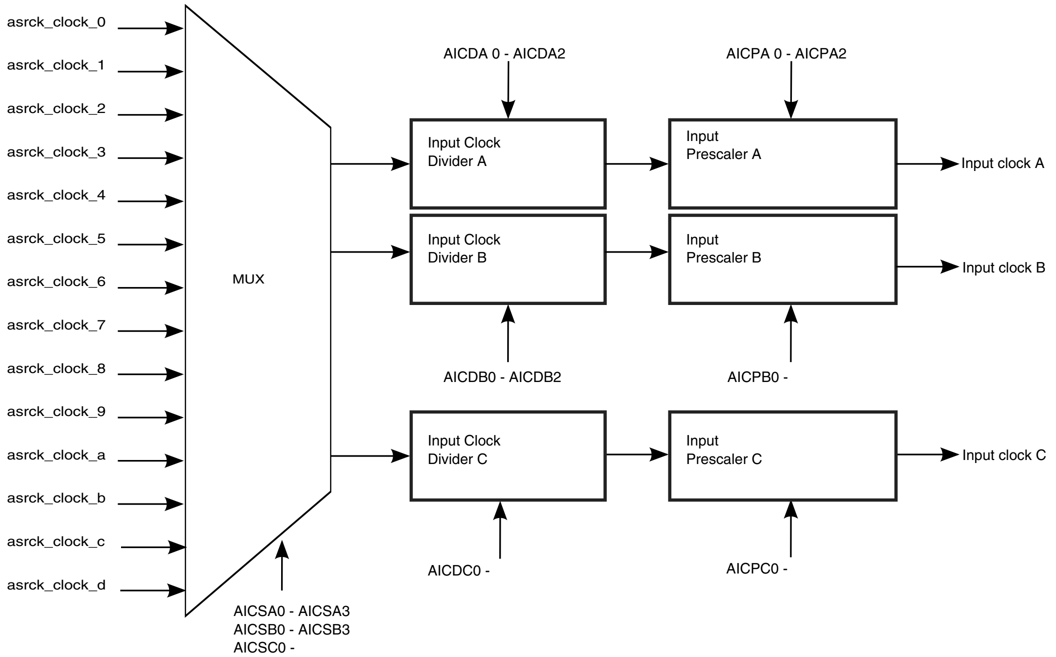
Post_Proc:

- 0 --- Post-processing Branch 1
- 1 --- Post-processing Branch 2
- 2 --- Post-processing Branch 3

53.5.1.2 Operation of the Filter

53.5.1.2.1 Support of Physical Clocks

This design supports physical sampling clocks. The clocks can be provided by Sony/ Phillips digital interface (SPDIF), Enhanced Serial Audio Interface (ESAI), Synchronus Audio Interface. , Core master clock derivative as ASRCK1 .



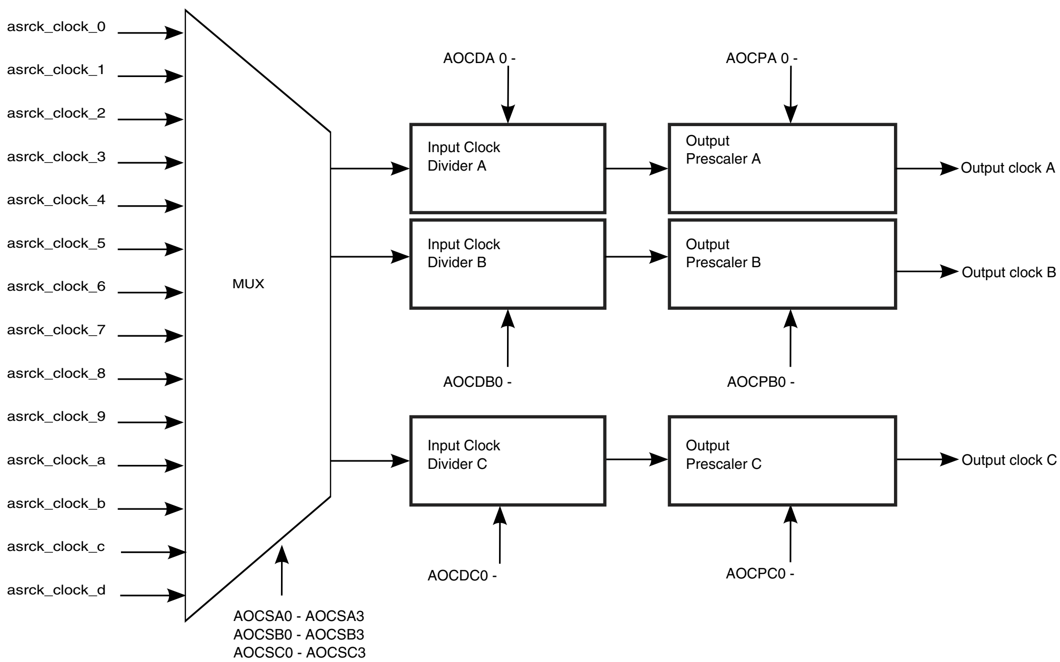


Figure 53-46. Clock Source Selector & Divider

Software can set the ASRC Clock Source Register (ASRCSR) and the Clock Divider Register to select the desired clock source and divide it to the needed sample rate clock for use by the ASRC. The clocks have the following restriction. If the prescaler is set to 1, the clock divider can only be set to 1 and the clock source must have a 50% duty cycle.

53.6 Startup Procedure

The following example shows the normal setup procedure for the ASRC block.

```

Chapter 54
Sony/Philips Digital Interface (SPDIF)

54.1 Introduction

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio. The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal and external components in the system such as ESAI ports, as well as external A/Ds or D/As, with clocking control provided via related registers.

As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

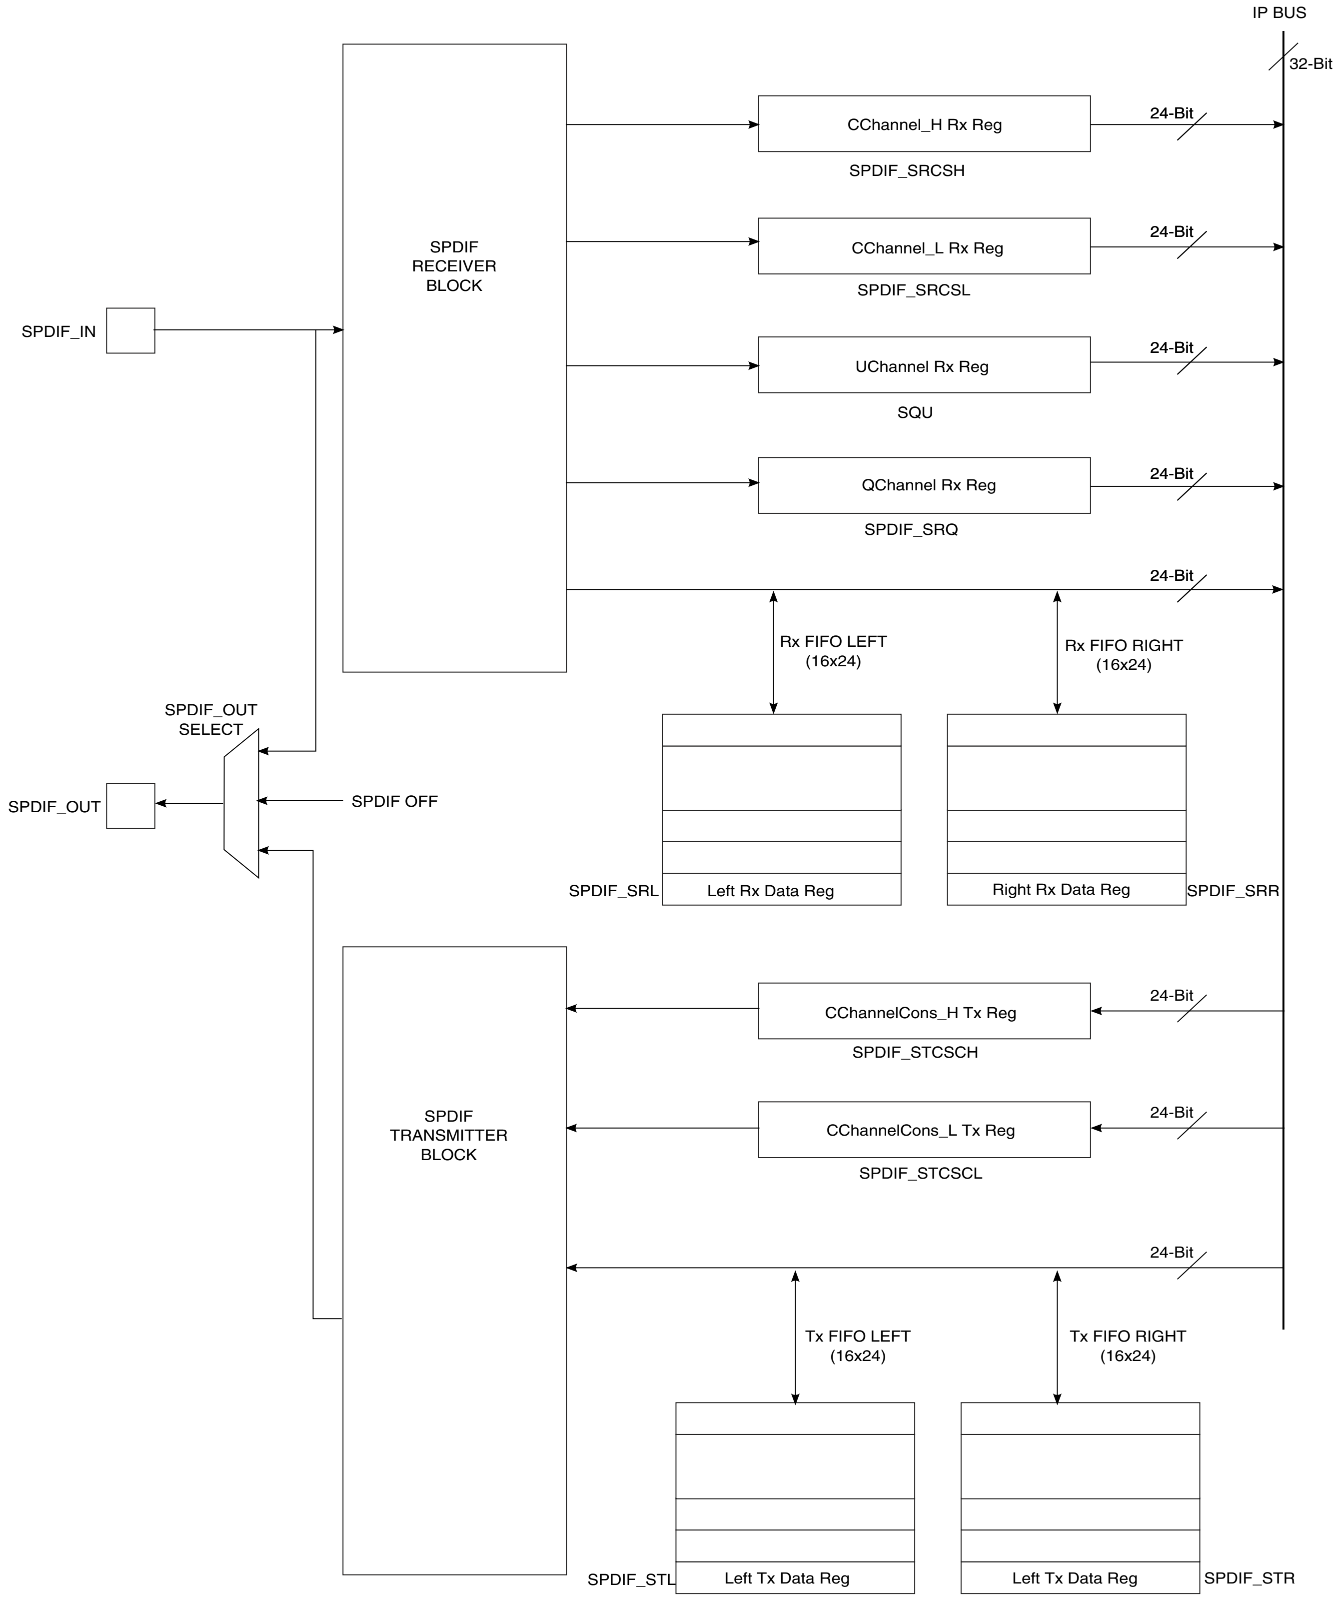

Figure 54-1. SPDIF Transceiver Data Interface Block Diagram

54.1.1 Overview

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphase mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphase bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock. Both the Rx clock and Tx clock are sent to the ASRC.

54.2 External Signal Description

Table 54-1. Signal Properties

Signal Name	Signal Type	Description
SPDIFIN	input	SPDIF Input Line IEC60958 data in biphase mark format.
SPDIFOUT	output	SPDIF Output Line IEC60958 data in biphase mark format. (Consumer C channel).

54.3 Functional Description

54.3.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception
- Channel Status bits Reception
- U Channel bits Reception
- Validity Flag Reception
- SPDIF Receiver Exception support
- SPDIF Lock Detection

54.3.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight. Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

- **SPDIF receiver data registers - Behavior on overrun, underrun**

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

- **SPDIF receiver data registers - Automatic resynchronization of FIFOs**

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

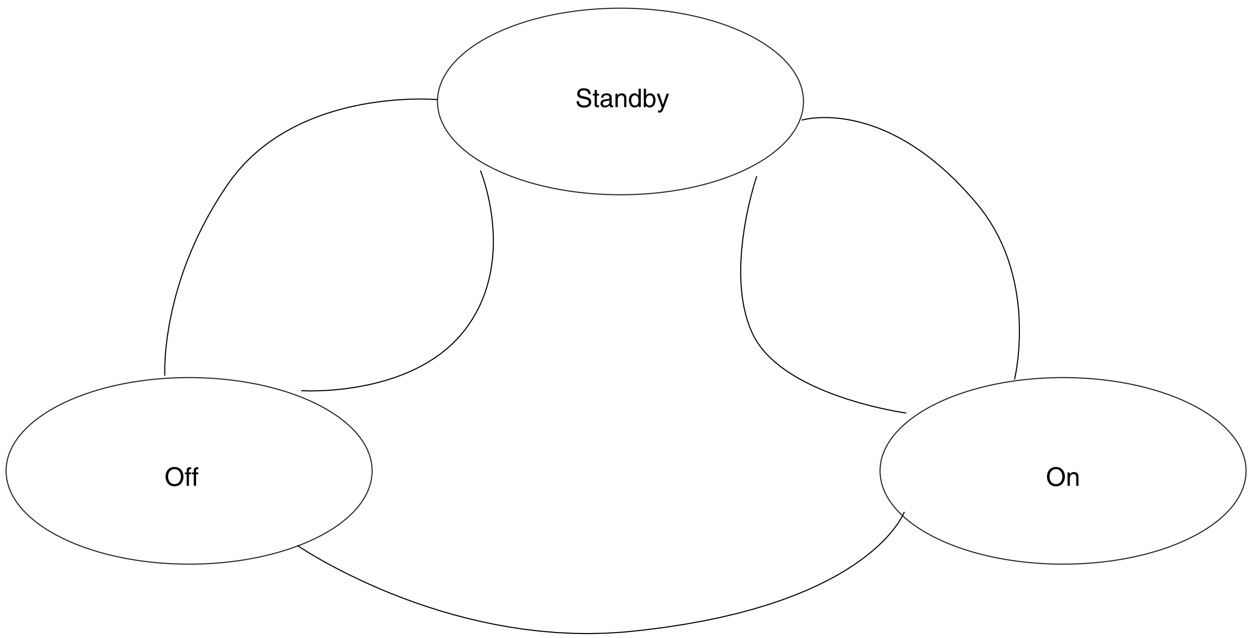

Figure 54-2. FIFO Auto-resync Controller State Machine

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right

sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

54.3.1.1.1 Application Note

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules:

- When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 Khz, approximately 10 micro-seconds. For 88 Khz, approximately 5 micro-seconds.)
- Write/read data to FIFO s at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.

SPDIF receiver - Additional features

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overrun
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overrun occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overrun" are set when one of the FIFOs do underrun or do overrun. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

Rx FIFO on and Rx FIFO reset

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

54.3.1.2 Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCChannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCChannel_l.

NOTE

Single DMA channel cannot service SPDIF Tx or Rx. Therefore, two DMA channels linked to each another are required to service SPDIF Rx request.

54.3.1.2.1 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the Interrupt register.

54.3.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

- **Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver**.

This mode is selected if UsyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

Table 54-2. Sync Control Bits

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-44	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated.Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8

UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.

- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.
- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.

- **Behavior of U Channel receive interface on incoming non-CD data**.

This mode is selected if UsyncMode, bit 1 in register CD Text control is set'0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

54.3.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

54.3.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt.

They are:

- Control Status channel change. Set when SPDIFRxCChannel1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.[1]
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.

1. The SPDIF input is a biphase/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

54.3.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 Khz up to 96 Khz. (fully compliant) and 96 Khz up to 176 Khz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

54.3.1.7 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin PLOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency.(For a 44.1 Khz input sampling frequency, the average pulse rate = 128 x 44.1 Khz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

54.3.1.8 Measuring Frequency of SPDIF_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.

FreqMeas[23:0] = FreqMeas_CLK / BUS_CLK * 2^{10} * GAIN.

For example, if the GAIN is selected as 8*210 (PhaseConfig[5:3] = 3'b011), the actual result

FreqMeas_CLK / BUS_CLK is equal to FreqMeas[23:0] / 2^{23}.

54.3.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is from either the osc_audio, ipg_baud_spdif_clk, hckt, or spdif_extclk, or frequency divided ipg_clk. A multiplexer is used to choose the clock source. The SPDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphase mark format, consisting of audio data, channel status.

54.3.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPDIF transmitter data registers - Behavior on overrun, underrun**

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPDIF transmitter data registers - Automatic resynchronization of FIFOs**

See Audio Data Reception.

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

54.3.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCChannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCChannelCons_l.

54.3.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF_SCR register.

54.4 Programmable Registers

SPDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_1000	SPDIF Configuration Register (SPDIF_SCR)	32	R/W	0000_0400h	54.4.1/3017

Field	Description
23–11 Reserved	This read-only field is reserved and always has the value 0.
10–7 ClkSrc_Sel	Clock source selection, all other settings not shown are reserved: **NOTE:** For the ClkSrc_Sel, each of the input clocks has the frequency of 64*Audio_Sample_Rate. And the Audio_Sample_Rate can be 32 KHz to 192 KHz. 0000 if (DPLL Locked) SPDIF_RxClk else extal_clk 0001 if (DPLL Locked) SPDIF_RxClk else pll4_div_clk 0010 if (DPLL Locked) SPDIF_RxClk else External audio clock input 0011 if (DPLL Locked) SPDIF_RxClk else mlb_clk 0100 if (DPLL Locked) SPDIF_Rxclk else esai_hckt 0101 extal_clk 0110 pll4_div_clk 0111 external audio clok 1000 mlb_clk 1001 esai_hckt 1010 if (DPLL Locked) SPDIF_RxClk else SAI0_TXBCLK 1011 if (DPLL Locked) SPDIF_RxClk else SAI3_TXBCLK 1100 sai0_txbclk 1101 sai3_txbclk
6 LOCK	LOCK bit to show that the internal DPLL is locked, read only
5–3 GainSel	Gain selection: 000 24*2**10 001 16*2**10 010 12*2**10 011 8*2**10 100 6*2**10 101 4*2**10 110 3*2**10
2–0 Reserved	This read-only field is reserved and always has the value 0.

54.4.4 InterruptEn Register (SPDIF_SIE)

The InterruptEn register (SPDIF_SIE) provides control over the enabling of interrupts.

Address: 4006_1000h base + Ch offset = 4006_100Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								0	Reserved		Lock	TxUnOv	TxResyn	CNew	ValNoGood
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SymErr	BitErr	Reserved			URxFul	URxOv	QRxFul	QRxOv	UQSync	UQErr	RxFIFOUnOv	RxFIFOResyn	LockLoss	TxEm	RxFIFOFul
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPDIF_SIE field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 Reserved	This read-only field is reserved and always has the value 0.
22–21 -	This field is reserved. Reserved, for InterruptStat/Clear return zeros when read, for InterruptEn, bit 23 also read zero
20 Lock	SPDIF receiver's DPLL is locked 0 Interrupt disabled 1 Interrupt enabled
19 TxUnOv	SPDIF Tx FIFO under/overrun 0 Interrupt disabled 1 Interrupt enabled
18 TxResyn	SPDIF Tx FIFO resync 0 Interrupt disabled 1 Interrupt enabled
17 CNew	SPDIF receive change in value of control channel 0 Interrupt disabled 1 Interrupt enabled

Table continues on the next page...

SPDIF_SIE field descriptions (continued)

Field	Description
16 ValNoGood	SPDIF validity flag no good 0 Interrupt disabled 1 Interrupt enabled
15 SymErr	SPDIF receiver found illegal symbol 0 Interrupt disabled 1 Interrupt enabled
14 BitErr	SPDIF receiver found parity bit error 0 Interrupt disabled 1 Interrupt disabled
13–11 -	This field is reserved. Reserved. Return zeros when read
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg. 0 Interrupt disabled 1 Interrupt enabled
9 URxOv	U Channel receive register overrun 0 Interrupt disabled 1 Interrupt enabled
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg. 0 Interrupt disabled 1 Interrupt enabled
7 QRxOv	Q Channel receive register overrun 0 Interrupt disabled 1 Interrupt enabled
6 UQSync	U/Q Channel sync found 0 Interrupt disabled 1 Interrupt enabled
5 UQErr	U/Q Channel framing error 0 Interrupt disabled 1 Interrupt enabled
4 RxFIFOUnOv	Rx FIFO underrun/overrun 0 Interrupt disabled 1 Interrupt enabled
3 RxFIFOResyn	Rx FIFO resync 0 Interrupt disabled 1 Interrupt enabled
2 LockLoss	SPDIF receiver loss of lock

Table continues on the next page...

SPDIF_SIE field descriptions (continued)

Field	Description
	0 Interrupt disabled 1 Interrupt enabled
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write toTx FIFO. 0 Interrupt disabled 1 Interrupt enabled
0 RxFIFOFul	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO. 0 Interrupt disabled 1 Interrupt enabled

54.4.5 InterruptStat Register (SPDIF_SIS)

The InterruptStat (SPDIF_SIS) register is a read only register that provides the status on interrupt operations.

Address: 4006_1000h base + 10h offset = 4006_1010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved											Lock	TxUnOv	TxResyn	CNew	ValNoGood
W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SymErr	BitErr	Reserved				URxOv	Reserved	QRxOv	UQSync	UQErr	RxFIFOUnOv	RxFIFOResyn	LockLoss	TxFIFOEmpty	RxFIFOFul
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPDIF_SIS field descriptions

Field	Description
31–21 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error

Table continues on the next page...

SPDIF_SIS field descriptions (continued)

Field	Description
13–10 -	This field is reserved. Reserved.
9 URxOv	U Channel receive register overrun
8 -	This field is reserved. Reserved
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxFIFOEmpty	Tx FIFO Empty Sets the Tx FIFO Empty flag.
0 RxFIFOFul	Rx FIFO full flag Sets the Rx FIFO full flag.

54.4.6 InterruptClear Register (SPDIF_SIC)

The InterruptClear (SPDIF_SIC) register is a write only register and is used to clear interrupts.

Address: 4006_1000h base + 10h offset = 4006_1010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W												Lock	TxUnOv	TxResyn	CNew	ValNoGood

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R			Reserved					Reserved							Reserved	
W	SymErr	BitErr					URxOv		QRxOv	UQSync	UQErr	RxFIFOUnOv	RxFIFOResyn	LockLoss		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPDIF_SIC field descriptions

Field	Description
31–21 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overrun
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–10 -	This field is reserved. Reserved.
9 URxOv	U Channel receive register overrun
8 -	This field is reserved. Reserved
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1–0 -	This field is reserved. Reserved.

54.4.7 SPDIFRxLeft Register (SPDIF_SRL)

SPDIFRxLeft register is an audio data reception register.

Address: 4006_1000h base + 14h offset = 4006_1014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

6–0 TxClk_DF	Divider factor (1-128) 0 divider factor is 1 1 divider factor is 2 127 divider factor is 128

Chapter 55
Display Control Unit (DCU4) (2D-ACE Functionality)

55.1 Display Control Unit (DCU)

55.2 Introduction

The Display Controller Unit (DCU4) module (2D-ACE functionality) is a system master that fetches graphics stored in internal or external memory and displays them on a TFT LCD panel. A wide range of panel sizes is supported and the timing of the interface signals is highly configurable. Graphics are read directly from memory and then blended in real-time, which allows for dynamic content creation with minimal CPU intervention. Graphics may be encoded in a variety of formats to optimise memory usage. The DCU4 also has the capability of displaying real-time video from an external video source.

55.2.1 Overview

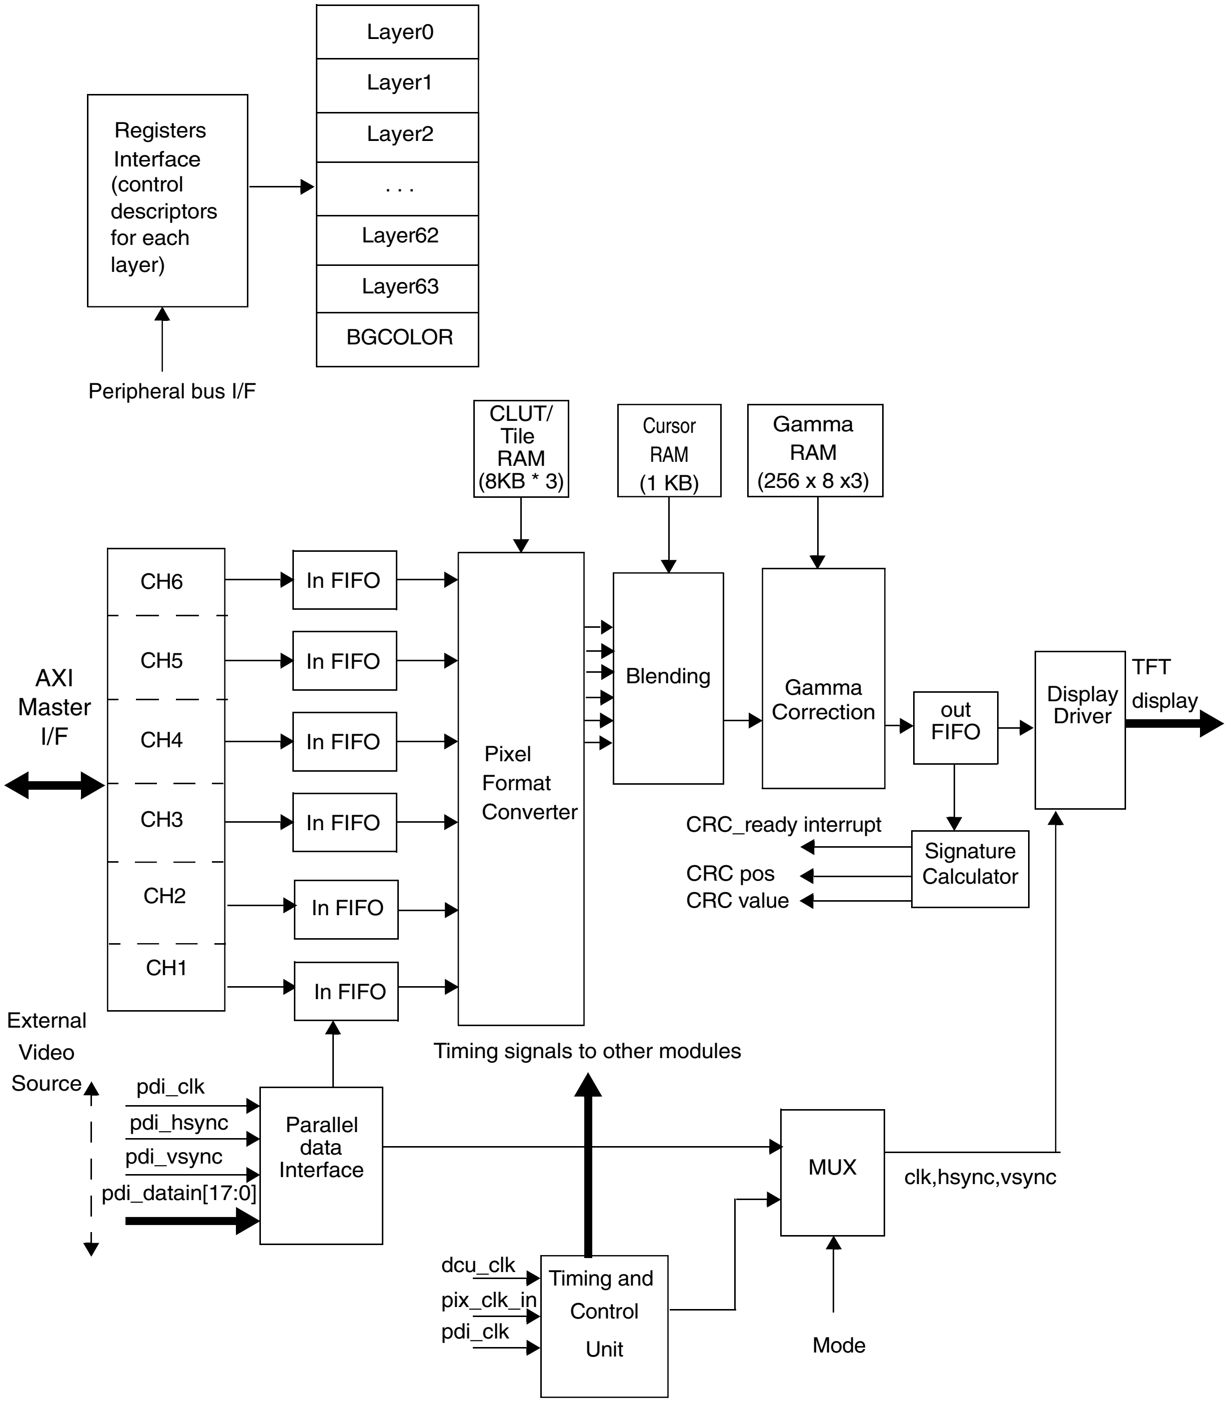

Figure 55-1. Display control unit block diagram

Figure 55-1 shows the DCU4 architecture. This comprises two distinct sections. The lower section shows the functional blocks of the DCU4 that fetch the graphic and video content and drive the TFT LCD panel. The upper section describes the user interface through which the user configures the graphical content of the TFT LCD panel.

The sections are analogous to the structure of communications modules, such as the FlexCAN, where one part of the module is configured to connect with the communications bus through bit-timing, parity, baud rate, etc., while a different part is used to store the data content and message identifiers.

The configuration of the lower section is dependent on the specific TFT LCD panel that is attached to the DCU4 outputs. In most cases, this is configured once for the hardware in use before the DCU4 is enabled. When active, this section automatically:

- Calculates the relevant graphical content for each pixel
- Fetches the source graphics from memory using its internal DMA channels (labelled CH1 to CH6) and stores the data in dedicated FIFO buffers
- Converts the graphic value of each fetched pixel into full quality color format (if required)
- Calculates the required pixel value by blending the values of up to six separate graphics
- Performs a gamma correction on the pixel value (if required)
- Sends the pixel value to the TFT LCD display over its data bus
- Sets flags to indicate end of frame, FIFO buffer threshold, and other status changes

The upper section describes the characteristics of the graphics to be displayed on the panel and how they are blended together. The DCU4 manages the graphical content of the panel through sets of registers called layers. There are 64 layers available in the DCU4 and each contains the following information:

- Horizontal and vertical size of graphic
- Position of graphic on the panel
- Address of graphic in memory
- Color encoding format and color palettes (if required)
- Type and depth of blending
- Range of colors identified for chroma blending
- Tile size
- Foreground and background colors for transparency encoded graphics

The values in these registers may be changed at any time, and the panel content will be updated either under software control or at an automatic point in the panel refresh cycle. The layers are set to a fixed priority, and this is used by the lower section to define which layers are blended, in which order, on the panel.

The upper section also contains configuration registers for a cursor graphic, the default background color, interrupt enables, test graphic, and simple register protection settings.

55.2.2 Features

The DCU4 has these features:

- Full RGB888 output to TFT LCD panel
- 64 graphics layers, a default background color layer and a cursor layer with integrated blinking option
- Blending of each pixel using up to 6 source layers dependent on size of panel
- Programmable panel size up to a maximum of XGA (1024x768) and a typical operating configuration of SVGA (800 x 600)
- Gamma correction with 8-bit resolution on each color component
- Safety mode for tagging pixels on highest priority layers
- Dedicated memory blocks to store a cursor and Color Look Up Tables (CLUTs)
- Temporal Dithering.

Each graphic layer has the following attributes:

- Can be placed with one pixel resolution in either axis
- Can also be placed in negative X and Y directions
- Supports multiple color-encoding formats including:
  - 1, 2, 4 and 8 bits per pixel indexed colors with alpha channel in look-up table
  - APAL8 indexed colors with alpha channel in each pixel
  - RGB565 and RGB888 direct colors without alpha channel
  - ARGB1555, ARGB4444, and BGRA8888 direct colors with an alpha channel
  - YCbCr422 format
- Alpha blending with 8-bit resolution
- Chroma-key blending for anti-mask encoding
- Multiple combined alpha and chroma-key blending modes
- Transparency modes for anti-aliased text and graphics
- Luminance mode for highlighting content
- Tile mode for efficient creation of textured background content

- Support for Run Length Encoding (RLE) compression
- Optimized mode for use with DDR memory

55.2.3 Modes of Operation

The DCU4 has four modes of operation:

- **DCU_OFF**: When in this mode, the DCU4 is turned off. All the logic in the design is put in reset state to reduce power.
- **NORMAL_MODE**: The DCU4 displays and blends the graphics specified by the layer descriptors.
- **PDI_MODE:** A mode which fetches video from an external video source and combines that with the graphics configured on the layers.
- **COLBAR_MODE**: Color bar generation for testing purposes.

55.3 External Signal Description

This section covers the DCU interface signals.

55.3.1 Overview

The choice of signals used depends on the configuration of the DCU4. All active signals must be selected by configuring the appropriate IOMUX registers.

The DCU4 has up to 22 input signals and up to 30 output signals, as shown in the following figure. The choice of signals used depends on the configuration of the DCU4. All active signals must be enabled by configuring the appropriate IOMUX registers.

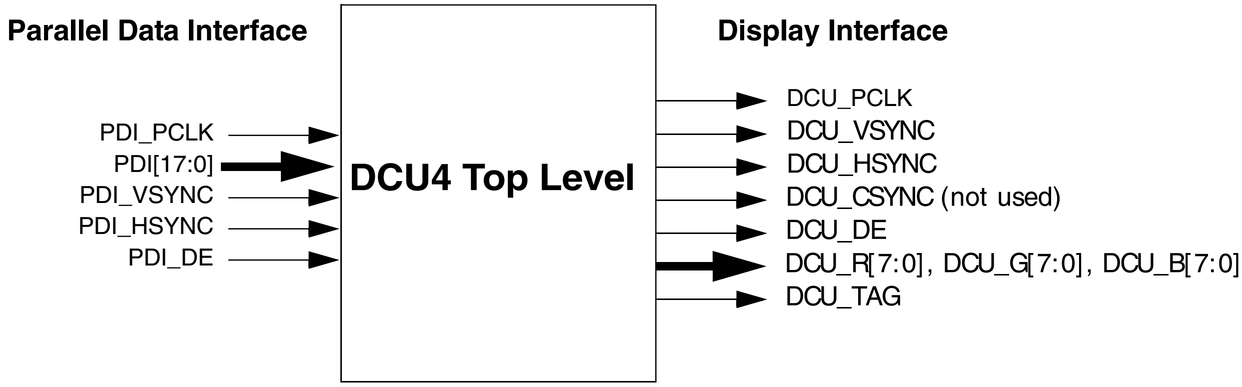

Figure 55-2. External Signals

55.3.2 Detailed Signal Descriptions

Table 55-1. Detailed Signal Descriptions

Signal	Direction	Description
Display Interface		
DCU_PCLK	OUT	Pixel clock used to drive the display panel
DCU_VSYNC	OUT	Vertical sync signal, indicating the beginning of a new frame
DCU_HSYNC	OUT	Horizontal sync signal, indicating the beginning of a new line
DCU_TAG	OUT	When high, this signal indicates that the pixel is tagged and an application can calculate CRC externally on this pixel.
DCU_DE	OUT	Data Enable. Qualifies the data output (dcu_ld)
DCU_R[7:0] DCU_G[7:0] DCU_B[7:0]	OUT	Red, green and blue data output.

55.4 DCU4 Memory Map

Table 55-2. DCU4 memory map

Parameter	Address Range
Register address space	0x0000 – 0x1FFF

Table continues on the next page...

Table 55-2. DCU4 memory map (continued)

Parameter	Address Range
Palette/Tile address space	0x2000 – 0x3FFF
Gamma_R address space	0x4000 – 0x43FF
Gamma_G address space	0x4400 – 0x47FF
Gamma_B address space	0x4800 – 0x4BFF
Cursor address space	0x4C00 – 0x4FFF

55.5 Memory Map and Registers

DCU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_8000	Control Descriptor Cursor 1 Register (DCU0_CTRLDESCCURSOR1)	32	R/W	0000_0000h	55.5.1/3101
4005_8004	Control Descriptor Cursor 2 Register (DCU0_CTRLDESCCURSOR2)	32	R/W	0000_0000h	55.5.2/3101
4005_8008	Control Descriptor Cursor 3 Register (DCU0_CTRLDESCCURSOR3)	32	R/W	0000_0000h	55.5.3/3102
4005_800C	Control Descriptor Cursor 4 Register (DCU0_CTRLDESCCURSOR4)	32	R/W	0000_0000h	55.5.4/3103
4005_8010	DCU4 Mode Register (DCU0_DCU_MODE)	32	R/W	0000_8000h	55.5.5/3104
4005_8014	Background Register (DCU0_BGND)	32	R/W	0000_0000h	55.5.6/3107
4005_8018	Display Size Register (DCU0_DISP_SIZE)	32	R/W	0000_0000h	55.5.7/3107
4005_801C	Horizontal Sync Parameter Register (DCU0_HSYN_PARA)	32	R/W	00C0_1803h	55.5.8/3108
4005_8020	Vertical Sync Parameter Register (DCU0_VSYN_PARA)	32	R/W	00C0_1803h	55.5.9/3109
4005_8024	Synchronize Polarity Register (DCU0_SYNPOL)	32	R/W	0000_0000h	55.5.10/ 3110
4005_8028	Threshold Register (DCU0_THRESHOLD)	32	R/W	0000_780Ah	55.5.11/ 3112
4005_802C	Interrupt Status Register (DCU0_INT_STATUS)	32	R/W	0000_0000h	55.5.12/ 3112
4005_8030	Interrupt Mask Register (DCU0_INT_MASK)	32	R/W	FCFF_5FFFh	55.5.13/ 3114
4005_8034	COLBAR_1 Register (DCU0_COLBAR_1)	32	R/W	FF00_0000h	55.5.14/ 3117
4005_8038	COLBAR_2 Register (DCU0_COLBAR_2)	32	R/W	FF00_00FFh	55.5.15/ 3118
4005_803C	COLBAR_3 Register (DCU0_COLBAR_3)	32	R/W	FF00_FFFFh	55.5.16/ 3118

Table continues on the next page...

DCU memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_8040	COLBAR_4 Register (DCU0_COLBAR_4)	32	R/W	FF00_FF00h	55.5.17/ 3119
4005_8044	COLBAR_5 Register (DCU0_COLBAR_5)	32	R/W	FFFF_FF00h	55.5.18/ 3120
4005_8048	COLBAR_6 Register (DCU0_COLBAR_6)	32	R/W	FFFF_0000h	55.5.19/ 3120
4005_804C	COLBAR_7 Register (DCU0_COLBAR_7)	32	R/W	FFFF_00FFh	55.5.20/ 3121
4005_8050	COLBAR_8 Register (DCU0_COLBAR_8)	32	R/W	FFFF_FFFFh	55.5.21/ 3122
4005_8054	Divide Ratio Register (DCU0_DIV_RATIO)	32	R/W	0000_0000h	55.5.22/ 3122
4005_8058	Sign Calculation 1 Register (DCU0_SIGN_CALC_1)	32	R/W	0000_0000h	55.5.23/ 3123
4005_805C	Sign Calculation 2 Register (DCU0_SIGN_CALC_2)	32	R/W	0000_0000h	55.5.24/ 3123
4005_8060	CRC Value Register (DCU0_CRC_VAL)	32	R/W	0000_0000h	55.5.25/ 3124
4005_8064	PDI Status Register (DCU0_PDI_STATUS)	32	R/W	0000_0000h	55.5.26/ 3125
4005_8068	PDI Status Mask Register (DCU0_PDI_STA_MSK)	32	R/W	0000_03FFh	55.5.27/ 3126

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_CTRLDESCCURSOR4 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 HWC_BLINK_ OFF	HWC blink register. Loads the counter value (number of frames) for which the cursor will remain turned OFF.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 EN_BLINK	Enable the cursor blink mode. 0 Disable the blink mode 1 Enable the blink mode

Table continues on the next page...

DCUx_CTRLDESCCURSOR4 field descriptions (continued)

Field	Description
7–0 HWC_BLINK_ON	HWC blink register. Loads the counter value (number of frames) for which the cursor will remain turned ON.

55.5.5 DCU4 Mode Register (DCUx_DCU_MODE)

NOTE

Note: A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	DCU_SW_RESET	EN_DITHER	ADDB		ADDG		ADDR		DDR_MODE	BLEND_ITER			PDI_SYNC_LOCK			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_DCU_MODE field descriptions

Field	Description
31 DCU_SW_RESET	Puts the DCU4 internal configuration into its reset state. This has the effect of stopping all display activity except the PCLK; graphics are not fetched and sent to the panel. 0 No action 1 All DCU4 internal registers are forced into their reset state. User registers are not affected
30 EN_DITHER	Enable dithering mode. 0 Disabled 1 Enabled
29–28 ADDB	Two-bit value to be added to pixel blue component for dithering.

Table continues on the next page...

DCUx_DCU_MODE field descriptions (continued)

Field	Description
27–26 ADDG	Two bit Value to be added with pixel green component for dithering.
25–24 ADDR	Two-bit value to be added to pixel red component for dithering.
23 DDR_MODE	Enables Special DDR Mode (see Section 54.6.9 Special DDR Mode"). Select BLEND_ITER = 6 when enabled. 0 Off 1 On
22–20 BLEND_ITER	Defines the maximum number of pixels which are blended in the pixel blend stack. 000 Reserved 001 Reserved 010 Two pixel blending (default) 011 Three pixel blending 100 Four pixel blending 101 Five pixel blending 110 Six plane blending 111 Reserved
19–16 PDI_SYNC_ LOCK	Defines the number of frames which should be received by the PDI validation state machine before it locks and sets the PDI_LOCK_DET bit in the PDI Status Register (see PDI Status Register (DCU_PDI_STATUS))
15 PDI_INTERPOL_ EN	Control Bit to decide whether the conversion from YCbCr 4:2:2 to 4:4:4 needs to be done using interpolation or Chroma value is same for two pixels. 0 Chroma value is same for two pixels 1 Interpolation is enabled
14 RASTER_EN	Enables raster scanning of pixel data including the VSYNC and HSYNC signals and the pixel data. This bit takes effect immediately and does not require a transfer to the frame timing logic. 0 Disabled 1 Enabled
13 PDI_EN	Enables the PDI. 0 Disabled 1 Enabled
12 PDI_BYTE_REV	Controls the byte ordering in Narrow Mode. 0 LSB is followed by MSB data 1 MSB is followed by LSB data
11 PDI_DE_MODE	Enables the PDI data Enable Mode. Here Data Enable is treated as an input. 0 Value on data Enable signal is ignored 1 Data enable controls the write to the PDI FIFO
10 PDI_NARROW_ MODE	Enables the PDI Narrow Mode. Refer to "Normal and narrow mode" section.

Table continues on the next page...

DCUx_DCU_MODE field descriptions (continued)

Field	Description
	0 Narrow Mode is Disabled 1 Narrow Mode is Enabled
9–8 PDI_MODE	Defines the different modes in which PDI is operating. 00 8-bit monochrome data input 01 16-bit RGB 565 format 10 18-bit RGB 666 data format 11 YCbCr data in 4:2:2 format
7 PDI_SLAVE_ MODE	Enables PDI slave Mode. 0 Disabled 1 Enabled
6 TAG_EN	Enables the calculation of CRC only on the safety layers. 0 CRC calculated over the whole area of interest (area of interest given by SIG_DESC registers) 1 Calculates CRC only on safety enabled layers
5 SIG_EN	Enables the signature calculator block. 0 Signature calculator is disabled 1 Signature calculator is enabled
4 RESERVED	This field is reserved. 0 External Synchronization. The PDI receives the SYNC (HSYNC, VSYNC) signals from external source. 1 Internal Synchronization. PDI extracts the SYNC information from the digital RGB data. **NOTE:** YCbCr Mode supports Internal Sync only. Therefore, when PDI_ MODE = 3, PDI_SYNC must be set to 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 EN_GAMMA	Enables/Disables the Gamma Correction. 0 Gamma correction is disabled 1 Gamma Correction is enabled
1–0 DCU_MODE	DCU operating mode. 00 DCU off (pixel clock active if enabled by I/O). 01 Normal mode. Panel content controlled by layer configuration. 10 Test mode. DCU disables all DMA fetches and all the pixels of an enabled layer take the value in the CLUT RAM selected by the respective LUOFFS field of control descriptor 4. 11 Color Bar Generation. Panel content controlled by color bar registers.

55.5.6 Background Register (DCUx_BGND)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								BGND_R								BGND_G								BGND_B							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_BGND field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 BGND_R	Red component of the default color displayed in the sectors where no layer is active.
15–8 BGND_G	Green component of the default color displayed in the sectors where no layer is active.
7–0 BGND_B	Blue component of the default color displayed in the sectors where no layer is active.

55.5.7 Display Size Register (DCUx_DISP_SIZE)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

NOTE

The device supports the panel size up to XGA (1024 x 768) only.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0					DELTA_Y											0									DELTA_X						
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_DISP_SIZE field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 DELTA_Y	Sets the display size vertical resolution (in pixels).
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–0 DELTA_X	Sets the display size horizontal resolution (in multiples of 16 pixels).

55.5.8 Horizontal Sync Parameter Register (DCUx_HSYN_PARA)

HSYN_PARA register sets timing parameters related to the horizontal synchronization signal generation. The fields FP_H, BP_H, and PW_H stand for HSYNC signal front-porch, back-porch, and active pulse width, respectively.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	BP_H									0		PW_H

DCUx_HSYN_PARA field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 BP_H	HSYNC back-porch pulse width (in pixel clock cycles). Pulse width has a minimum value of 1.
21–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–11 PW_H	HSYNC active pulse width (in pixel clock cycles).
10–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DCUx_HSYN_PARA field descriptions (continued)

Field	Description
8–0 FP_H	HSYNC front-porch pulse width (in pixel clock cycles). Pulse width has a minimum value of 1.

55.5.9 Vertical Sync Parameter Register (DCUx_VSYN_PARA)

VSYN_PARA register sets timing parameters related to the vertical synchronization signal generation. The fields FP_V, BP_V, and PW_V stand for VSYNC signal front-porch, back-porch, and active pulse width, respectively.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DCUx_VSYN_PARA field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 BP_V	VSYNC back-porch pulse width (in horizontal line cycles). Pulse width has a minimum value of 1.
21–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–11 PW_V	VSYNC active pulse width (in horizontal line cycles).
10–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–0 FP_V	VSYNC front-porch pulse width (in horizontal line cycles). Pulse width has a minimum value of 1.

55.5.10 Synchronize Polarity Register (DCUx_SYNPOL)

The SYNPOL register selects the polarity for the DCU synchronisation signals (HSYNC and VSYNC).

Address: Base address + 24h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_SYNPOL field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 INV_PDI_DE	Polarity of PDI input data Enable. 0 DE is active low 1 DE is active high

Table continues on the next page...

DCUx_SYNPOL field descriptions (continued)

Field	Description
9 INV_PDI_HS	Polarity of PDI input HSYNC. 0 HSYNC is active low 1 HSYNC is active high
8 INV_PDI_VS	Polarity of PDI input VSYNC. 0 VSYNC is active low 1 VSYNC is active high
7 INV_PDI_CLK	Polarity of PDI input Clock. 0 DCU4 samples data on the rising edge 1 DCU4 samples data on the falling edge
6 INV_PXCK	Polarity change of Pixel Clock. 0 Display samples data on the falling edge 1 Display samples data on the rising edge
5 NEG	Indicates if value at the output (pixel data output) needs to be negated. 0 Output is to remain same 1 Output to be negated
4 RESERVED	This field is reserved.
3 RESERVED	This field is reserved.
2 RESERVED	This field is reserved.
1 INV_VS	Invert Vertical synchronization signal. 0 VSYNC signal not inverted (active HIGH). 1 Invert VSYNC signal (active LOW).
0 INV_HS	Invert Horizontal synchronization signal. 0 HSYNC signal not inverted (active HIGH). 1 Invert HSYNC signal (active LOW).

55.5.11 Threshold Register (DCUx_THRESHOLD)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 28h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0					LS_BF_VS										
W

R	OUT_BUF_HIGH								OUT_BUF_LOW							
W																
Reset	0	1	1	1	1	0	0	0	0	0	0	0	1	0	1	0

DCUx_THRESHOLD field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 LS_BF_VS	Lines before VS_BLANK threshold value. The LS_BF_VS status flag (in INT_STATUS) is set this number of lines before the VS_BLANK signal is asserted.
15–8 OUT_BUF_HIGH	Output buffer high threshold (in pixels). When the output buffer exceeds this value the datapath clock is suspended.
7–0 OUT_BUF_LOW	Output buffer filling low Threshold (in pixels).This value is used to generate the underrun exception (UNDRUN in INT_STATUS).

55.5.12 Interrupt Status Register (DCUx_INT_STATUS)

See Interrupt generation for a description of how the DCU4 collects interrupt events into different source groups.

Unless stated otherwise, the flags in this register are cleared by writing 1 to the relevant bit.

Address: Base address + 2Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DCUx_INT_STATUS field descriptions

Field	Description
31 P6_EMPTY	Interrupt flag to indicate that the FIFO in position 6 in the pixel blend stack underflowed.
30 P5_EMPTY	Interrupt flag to indicate that the FIFO in position 5 in the pixel blend stack underflowed.
29 P4_EMPTY	Interrupt flag to indicate that the FIFO in position 4 in the pixel blend stack underflowed.
28 P3_EMPTY	Interrupt flag to indicate that the FIFO in position 3 in the pixel blend stack underflowed.
27 P2_EMPTY	Interrupt flag to indicate that the FIFO in position 2 in the pixel blend stack underflowed.
26 P1_EMPTY	Interrupt flag to indicate that the FIFO in position 1 (lowest) in the pixel blend stack underflowed.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 P6_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 6 in the pixel blend stack.
22 P6_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 6 in the pixel blend stack.
21 P5_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 5 in the pixel blend stack.
20 P5_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 5 in the pixel blend stack.
19 P4_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 4 in the pixel blend stack.
18 P4_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 4 in the pixel blend stack.
17 P3_FIFO_HI_FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 3 in the pixel blend stack.
16 P3_FIFO_LO_FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 3 in the pixel blend stack.

Table continues on the next page...

DCUx_INT_STATUS field descriptions (continued)

Field	Description
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 DMA_TRANS_ FINISH	Interrupt flag, which indicates that the DCU4 DMA has fetched the last pixel of data from the memory.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 LYR_TRANS_ FINISH	Interrupt flag to indicate that the transfer is complete of layer configuration from the layer control descriptor registers into the DCU4 functional block
11 IPM_ERROR	Interrupt flag, which indicates that an error has occured in the Magenta line transaction.
10 PROG_END	Interrupt flag which indicates that the DCU4 has begun to transfer layer configuration from the layer control descriptor registers into the DCU4 functional block. Any register modification after this time and before LYR_TRANS_FINISH is asserted may or may not be included in this transfer.
9 P2_FIFO_HI_ FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 2 in the pixel blend stack.
8 P2_FIFO_LO_ FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 2 in the pixel blend stack.
7 P1_FIFO_HI_ FLAG	Interrupt flag to indicate that the high threshold has been reached in the FIFO in position 1 (lowest) in the pixel blend stack.
6 P1_FIFO_LO_ FLAG	Interrupt flag to indicate that the low threshold has been reached in the FIFO in position 1 (lowest) in the pixel blend stack.
5 CRC_ OVERFLOW	Interrupt signal to indicate that CRC_ready has not been serviced and CRC has been calculated for the next frame
4 CRC_READY	Interrupt flag to indicate CRC calculation is done and ready to be compared with precomputed CRC value by the software.
3 VS_BLANK	Interrupt signal to indicate vertical blanking period. This is the period in which all the registers that affect the visible state of the layers need to be latched. This is needed so that CPU writes to the register while the display is being updated does not cause any errors. Interrupt can be cleared by writing 1 to this bit..
2 LS_BF_VS	Interrupt flag to indicate the Lines Before VS_BLANK event has been reached. The LS_BF_VS field in the Threshold register defines the timing of the event.
1 UNDRUN	Interrupt flag to indicate the output buffer underrun condition. Asserted when the panel needs data and the output buffer level is lower than or equal to the OUT_BUF_LOW threshold. Flag is cleared when the data in the output buffer is greater than threshold and CPU writes 1 to this bit.
0 VSYNC	Interrupt flag to indicate that the vertical synchronization phase has begun. If enabled, an interrupt is generated at the beginning of a frame.

55.5.13 Interrupt Mask Register (DCUx_INT_MASK)

This register enables or masks the corresponding interrupt.

For each individual interrupt bit:

0 Not masked

1 Interrupt is masked

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DCUx_INT_MASK field descriptions

Field	Description
31 M_P6_EMPTY	Mask for P6_EMPTY interrupt flag.
30 M_P5_EMPTY	Mask for P5_EMPTY interrupt flag.
29 M_P4_EMPTY	Mask for P4_EMPTY interrupt flag.
28 M_P3_EMPTY	Mask for P3_EMPTY interrupt flag.
27 M_P2_EMPTY	Mask for P2_EMPTY interrupt flag.
26 M_P1_EMPTY	Mask for P1_EMPTY interrupt flag.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 M_P6_FIFO_HI_FLAG	Mask for P6_FIFO_HI_FLAG interrupt flag.
22 M_P6_FIFO_LO_FLAG	Mask for P6_FIFO_LO_FLAG interrupt flag.

Table continues on the next page...

DCUx_INT_MASK field descriptions (continued)

Field	Description
21 M_P5_FIFO_HI_ FLAG	Mask for P5_FIFO_HI_FLAG interrupt flag.
20 M_P5_FIFO_LO_ FLAG	Mask for P5_FIFO_LO_FLAG interrupt flag.
19 M_P4_FIFO_HI_ FLAG	Mask for P4_FIFO_HI_FLAG interrupt flag.
18 M_P4_FIFO_LO_ FLAG	Mask for P4_FIFO_LO_FLAG interrupt flag.
17 M_P3_FIFO_HI_ FLAG	Mask for P3_FIFO_HI_FLAG interrupt flag.
16 M_P3_FIFO_LO_ FLAG	Mask for P6_FIFO_LO_FLAG interrupt flag.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 M_DMA_ TRANS_FINISH	Mask for DMA_TRANS_FINISH interrupt flag.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 M_LYR_TRANS_ FINISH	Mask for SHDW_CMPLT interrupt flag.
11 M_IPM_ERROR	Mask for IPM_ERROR interrupt flag.
10 M_PROG_END	Mask for PROG_END interrupt flag.
9 M_P2_FIFO_HI_ FLAG	Mask for P2_FIFO_HI_FLAG interrupt flag.
8 M_P2_FIFO_LO_ FLAG	Mask for P2_FIFO_LO_FLAG interrupt flag.
7 M_P1_FIFO_HI_ FLAG	Mask for P1_FIFO_HI_FLAG interrupt flag.
6 M_P1_FIFO_LO_ FLAG	Mask for P1_FIFO_LO_FLAG interrupt flag.
5 M_CRC_ OVERFLOW	Mask for CRC_OVERFLOW interrupt flag.

Table continues on the next page...

DCUx_INT_MASK field descriptions (continued)

Field	Description
4 M_CRC_READY	Mask for CRC_READY interrupt flag.
3 M_VS_BLANK	Mask for VS_BLANK interrupt flag.rupt can be cleared by writing 1 to this bit..
2 M_LS_BF_VS	Mask for LS_BF_VS interrupt flag.
1 M_UNDRUN	Mask for M_UNDRUN interrupt flag.
0 M_VSYNC	Mask for VSYNC interrupt flag.

55.5.14 COLBAR_1 Register (DCUx_COLBAR_1)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 34h offset

Bit	31–24	23–16	15–8	7–0
R	1	COLBAR_1_R	COLBAR_1_G	COLBAR_1_B
W				
Reset	1 1 1 1 1 1 1 1	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

DCUx_COLBAR_1 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_1_R	Red component value.
15–8 COLBAR_1_G	Green component value.
7–0 COLBAR_1_B	Blue component value.

55.5.15 COLBAR_2 Register (DCUx_COLBAR_2)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCUx_COLBAR_2 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_2_R	Red component value.
15–8 COLBAR_2_G	Green component value.
7–0 COLBAR_2_B	Blue component value.

55.5.16 COLBAR_3 Register (DCUx_COLBAR_3)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 3Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	1								COLBAR_3_R								COLBAR_3_G								COLBAR_3_B							
W

DCUx_COLBAR_3 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_3_R	Red component value.
15–8 COLBAR_3_G	Green component value.
7–0 COLBAR_3_B	Blue component value.

55.5.17 COLBAR_4 Register (DCUx_COLBAR_4)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCUx_COLBAR_4 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_4_R	Red component value.
15–8 COLBAR_4_G	Green component value.
7–0 COLBAR_4_B	Blue component value.

55.5.18 COLBAR_5 Register (DCUx_COLBAR_5)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 44h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCUx_COLBAR_5 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_5_R	Red component value.
15–8 COLBAR_5_G	Green component value.
7–0 COLBAR_5_B	Blue component value.

55.5.19 COLBAR_6 Register (DCUx_COLBAR_6)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 48h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCUx_COLBAR_6 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_6_R	Red component value.
15–8 COLBAR_6_G	Green component value.
7–0 COLBAR_6_B	Blue component value.

55.5.20 COLBAR_7 Register (DCUx_COLBAR_7)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 4Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCUx_COLBAR_7 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_7_R	Red component value.
15–8 COLBAR_7_G	Green component value.
7–0 COLBAR_7_B	Blue component value.

55.5.21 COLBAR_8 Register (DCUx_COLBAR_8)

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 50h offset

Bit	31–24	23–16	15–8	7–0
R	1	COLBAR_8_R	COLBAR_8_G	COLBAR_8_B
W				
Reset	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1

DCUx_COLBAR_8 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
23–16 COLBAR_8_R	Red component value.
15–8 COLBAR_8_G	Green component value.
7–0 COLBAR_8_B	Blue component value.

55.5.22 Divide Ratio Register (DCUx_DIV_RATIO)

This register for vertical/horizontal size of the area for CRC calculation.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 54h offset

Bit	31–8	7–0
R	0	DIV_RATIO
W		
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

DCUx_DIV_RATIO field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–0 DIV_RATIO	Specifies the divide value for the input clock. Used to generate the pixel clock to support different types of displays. To divide by N, set the DIV_RATIO to (N – 1).

55.5.23 Sign Calculation 1 Register (DCUx_SIGN_CALC_1)

This register specifies the vertical/horizontal size of the area for the CRC calculation.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 58h offset

Bit	31–27	26–16	15–11	10–0
R	0	SIG_VER_SIZE	0	SIG_HOR_SIZE
W				
Reset	0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0

DCUx_SIGN_CALC_1 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 SIG_VER_SIZE	Vertical size of the window of interest of pixels for CRC calculation (in pixels).
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–0 SIG_HOR_SIZE	Horizontal size of window of interest of pixels for CRC calculations (in pixels).

55.5.24 Sign Calculation 2 Register (DCUx_SIGN_CALC_2)

This register specifies the position of the window of interest for the CRC calculation

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 5Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0					SIG_VER_POS											0					SIG_HOR_POS										
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_SIGN_CALC_2 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–16 SIG_VER_POS	Vertical position of the window of interest of pixels for CRC calculation (in pixels).
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–0 SIG_HOR_POS	Horizontal position of window of interest of pixels for CRC calculation (in pixels).

55.5.25 CRC Value Register (DCUx_CRC_VAL)

This register contains the result of the CRC calculation for the value of the pixels on the safety layers.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CRC_VAL																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_CRC_VAL field descriptions

Field	Description
31–0 CRC_VAL	The result of the CRC calculation for the value of the pixels on the safety layers

55.5.26 PDI Status Register (DCUx_PDI_STATUS)

Address: Base address + 64h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_PDI_STATUS field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 PDI_BLANKING_ERR	Status bit to inform the software that 80h,10h sequence is not present during the blanking period in internal sync mode. 0 Correct data sequence present in blanking period. 1 Correct data sequence not present in blanking period.
8 PDI_ECC_ERR2	Status bit to inform the software about multibit bit error that is detected. 0 Multibit ECC error is not detected 1 Multibit ECC error detected
7 PDI_ECC_ERR1	Status bit to inform the software about one bit error is detected. 0 One bit ECC error is not detected. 1 One bit ECC error detected
6 PDI_LOCK_LOST	Status bit to inform the software that frame lock is lost. 0 Frame is locked 1 Frame lock is lost
5 PDI_LOCK_DET	Status bit to inform the software PDI is frame locked to the camera interface. 0 Waiting for frame to lock 1 Frame lock is detected
4 PDI_VSYNC_DET	Status bit to inform the software that vsync for the camera data has been detected.

Table continues on the next page...

DCUx_PDI_STATUS field descriptions (continued)

Field	Description
	0 pdi_vsync not detected 1 pdi_vsync is detected
3 PDI_HSYNC_ DET	Status bit to inform the software that hsync for the camera data has been detected. 0 pdi_hsync not detected 1 pdi_hsync is detected
2 PDI_DE_DET	Status bit to inform the software that data Enable for the camera data has been detected. 0 pdi_de not detected 1 pdi_de is detected
1 PDI_CLK_LOST	Status bit to inform the software that pdi_clk is lost. 0 pdi_clk is present 1 pdi_clk is lost
0 PDI_CLK_DET	Status bit to inform the software that clock for the camera data has been detected. 0 pdi_clk not detected 1 pdi_clk is detected

55.5.27 PDI Status Mask Register (DCUx_PDI_STA_MSK)

This register enables or masks the corresponding interrupt.

For each individual interrupt bit:

0 Not masked

1 Interrupt is masked

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DCUx_PDI_STA_MSK field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 M_PDI_ BLANKING_ERR	Mask for PDI_BLANKING_ERR interrupt flag.
8 M_PDI_ECC_ ERR2	Mask for PDI_ECC_ERR2 interrupt flag.
7 M_PDI_ECC_ ERR1	Mask for PDI_ECC_ERR1 interrupt flag.
6 M_PDI_LOCK_ LOST	Mask for PDI_LOCK_LOST interrupt flag.
5 M_PDI_LOCK_ DET	Mask for PDI_LOCK_DET interrupt flag.
4 M_PDI_VSYNC_ DET	Mask for PDI_VSYNC_DET interrupt flag.
3 M_PDI_HSYNC_ DET	Mask for PDI_HSYNC_DET interrupt flag.
2 M_PDI_DE_DET	Mask for PDI_DE_DET interrupt flag.
1 M_PDI_CLK_ LOST	Mask for PDI_CLK_LOST interrupt flag.
0 M_PDI_CLK_ DET	Mask for PDI_CLK_DET interrupt flag.

55.5.28 Parameter Error Status 1 Register (DCUx_PARR_ERR_STATUS1)

An error in a layer can occur under the following conditions:

- Number of pixels in a tile > maximum tile memory size when internal tile memory mode is in use.
- There is a non-valid horizontal size and color format combination. See Layer size and positioning for details.

These errors are grouped into a single bit error for each layer. The parameter error specific to each layer is signalled only when the layer is enabled.

Address: Base address + 6Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	L[31:0]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_PARR_ERR_STATUS1 field descriptions

Field	Description
31–0 L[31:0]	For each individual interrupt: 0 Parameter error is not set 1 Parameter error is set

55.5.29 Parameter Error Status 2 Register (DCUx_PARR_ERR_STATUS2)

An error in a layer can occur under the following conditions:

- Number of pixels in a tile > maximum tile memory size when internal tile memory mode is in use.
- There is a non-valid horizontal size and color format combination. See Layer size and positioning for details.

These errors are grouped into a single bit error for each layer. The parameter error specific to each layer is signalled only when the layer is enabled.

For each individual interrupt:

0 Parameter error is not set

1 Parameter error is set

Address: Base address + 70h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	L[63:32]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_PARR_ERR_STATUS2 field descriptions

Field	Description
31–0 L[63:32]	For each individual interrupt: 0 Parameter error is not set 1 Parameter error is set

55.5.30 Parameter Error Status 3 Register (DCUx_PARR_ERR_STATUS3)

DISP_ERR occurs when the size of display (height or width) is set to zero or when the pulse width of hsync/vsync is programmed as zero.

SIG_ERR occurs when the area of interest for calculating CRC value is programmed with values which are outside the display.

HWC_ERR occurs if size of cursor programmed is greater than memory size (256 x 32). See Hardware cursor for further details on how cursor can be programmed.

RLE_ERR occurs when more than one layer has its RLE_EN bit set (Control Descriptor 4).

Address: Base address + 7Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DCUx_PARR_ERR_STATUS3 field descriptions

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 RLE_ERR	Error signal to indicate that more than one layer has RLE mode enabled.
2 HWC_ERR	Interrupt signal to indicate HWC error. This can occur if HWC position is out of display area or cursor memory is bigger than the HWC size. When this occurs, the HWC is disabled.

Table continues on the next page...

DCUx_PARR_ERR_STATUS3 field descriptions (continued)

Field	Description
1 SIG_ERR	Interrupt occurs whenever the area of interest specified by SIG_CALC register is outside the display size.
0 DISP_ERR	Interrupt occurs whenever width and height of display, pulse width (both vertical and horizontal sync) value is 0.

55.5.31 Mask Parameter Error Status 1 Register (DCUx_MASK_PARR_ERR_STATUS1)

This register enables or masks the corresponding interrupt.

For each individual interrupt bit:

0 Not masked

1 Interrupt is masked

Address: Base address + 80h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCUx_MASK_PARR_ERR_STATUS3 field descriptions

Field	Description
31–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 M_RLE_ERR	Mask for RLE_ERR interrupt flag.
2 M_HWC_ERR	Mask for HWC_ERR interrupt flag.
1 M_SIG_ERR	Mask for SIG_ERR interrupt flag.
0 M_DISP_ERR	Mask for DISP_ERR interrupt flag.

55.5.34 Threshold Input 1 Register (DCUx_THRESHOLD_INP_BUF_1)

This is the threshold configuration register for FIFO buffers 1 and 2. Note: A write to this register does not take effect until the value is transferred to the frame timing logic - see 43.5.4.2 Transfer of DCU Configuration.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 94h offset

R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCUx_UPDATE_MODE field descriptions

Field	Description
31 MODE	Do not set the MODE bit while the READREG is also set as this will block automatic updates. Do not set the MODE bit and the READREG register in the same write operation.

Table continues on the next page...

DCUx_UPDATE_MODE field descriptions (continued)

Field	Description
	The first frame transfer must be initiated manually using the READREG bit. Subsequent transfers can be performed automatically or manually. 0 Transfer of register values during vertical blanking period only when READREG is set 1 Automatic transfer of register values during vertical blanking period
30 READREG	When the MODE bit is clear this bit is a control bit which can be written to initiate a transfer of register value during the next vertical blanking period. 1'b1: (MODE=0) Transfer register values on next vertical blanking period. **NOTE:** If a transfer is underway, it is possible that changes to layer control descriptor values may be included in the transfer. 0 (MODE=0) No transfer scheduled. When the MODE bit is set, this bit is a status bit which indicates when a register transfer is underway. (MODE=1) No transfer is underway. 1 (MODE=0) Transfer register values on next vertical blanking period. (MODE=1) Register value transfer is underway.
29–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.5.49 Underrun Register (DCUx_UNDERRUN)

Address: Base address + D0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

25–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.5.58 Control Descriptor Ln_0 Register (DCUx_CTRLDESCL*n*_1)

This register sets the height and width of the layer associated with the register.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 200h offset + (64d × i), where i=0d to 63d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- This register resides in RAM, so reset values are undefined.

DCUx_CTRLDESCL*n*_1 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DCUx_CTRLDESCL*n*_1 field descriptions (continued)

Field	Description
26–16 HEIGHT	Height of the layer in pixels.
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–0 WIDTH	Width of the layer (in pixels). The layer width must be in multiples of the number of pixels that can be stored in 32 bits, and therefore differs depending on color encoding. For example, if 2 bits per pixel format is used, then the layer width must be configured in multiples of 16. See Layer size and positioning .

55.5.59 Control Descriptor Ln_1 Register (DCUx_CTRLDESCL*n*_2)

This register sets the origin (top/left) of the layer associated with the register.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 204h offset + (64d × i), where i=0d to 63d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- This register resides in RAM, so reset values are undefined.

DCUx_CTRLDESCL*n*_2 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–16 POSY	Two's complement signed value setting the vertic al position of top row of the layer, where 0 is the top row of the panel. Positive values are below and negative values are above the top row of the panel.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–0 POSX	Two's complement signed value setting the horizontal position of left hand column of the layer, where 0 is the left-hand column of the panel. Positive values are to the right and negative values are to the left the left-hand column of the panel.

55.5.60 Control Descriptor Ln_2 Register (DCUx_CTRLDESCL*n*_3)

This register sets the beginning address of layer data.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 208h offset + (64d × i), where i=0d to 63d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCUx_CTRLDESCL*n*_4 field descriptions

Field	Description
31 EN	Enable the layer. 0 OFF 1 ON
30 TILE_EN	Enable the Tile Mode. This bit is available only for layer numbers 0 through 7 and 56 through 63. For the rest of the layers this bit is reserved and returns zero. 0 OFF 1 ON
29 DATA_SEL	Selects the Tile data either from MCU memory or CLUT. This bit is available only for layer numbers 0 through 7 and 56 through 63. For the rest of the layers this bit is reserved and returns zero. 0 Tile Mode data resides in the MCU memory 1 Tile mode data resides in the CLUT
28 SAFETY_EN	Safety Mode Enable Bit. Valid only for layer 0 and layer 1. For registers of all other layers, this should be set to 0. 0 Safety Mode is disabled 1 Safety Mode is enabled for this layer
27–20 TRANS	Transparency Level. Specifies the alpha value for the layer. This value may be used by the blending engine to blend pixels on this layer. Value can vary between 0-255 iwhere 0 is completely transparent adn 255 is completely opaque.
19–16 BPP	Layer encoding format (bit per pixel) 0000 1 bpp 0001 2 bpp 0010 4 bpp 0011 8 bpp 100 16 bpp (RGB565) 0101 24 bpp 0110 32 bpp (ARGB8888) 0111 Transparency mode 4 bpp 1000 Transparency mode 8bpp 1001 Luminance offset mode 4 bpp 1010 Luminance offset mode 8 bpp 1011 16 bpp (ARGB1555) 1100 16 bpp (ARGB4444) 1101 16 bpp (APAL8 mode) 1110 YCbCr422 (the blend engine allows only a single YCbCr layer in any blend operation) 1111 Reserved
15 RLE_EN	Enable RLE mode for layer.

Table continues on the next page...

DCUx_CTRLDESCL*n*_4 field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
14–4 LUOFFS	Look Up Table offset. Value gives the offset to the start address of the CLUT or tile (when used in internal tile mode) in the CLUT/TILE RAM.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 BB	Chroma Keying. 0 OFF 1 ON
1–0 AB	Alpha Blending. 00 No alpha Blending 01 Blend only the pixels selected by chroma keying in case BB=1'b1 10 Blend the whole frame 11 Same functionality as 2'b00

55.5.62 Control Descriptor Ln_4 Register (DCUx_CTRLDESCL*n*_5)

This register sets the maximum Chroma Keying values for RGB.

Refer to Layer size and positioning for a description of Chroma Keying.

NOTE

A write to this register does not take effect until the value is transferred to the frame timing logic - see Transfer of DCU Configuration .

Address: Base address + 210h offset + (64d × i), where i=0d to 63d

55.6 Functional Description

The DCU4 is a master on the NIC; it fetches graphic source information directly from memory and dynamically performs blending and bit-bliting operations before delivering data to a TFT LCD panel.

55.6.1 Graphic sources

As the DCU4 is a master on the NIC, it can access directly any memory or device connected to the NIC as a slave. This includes all on-chip RAM, and any slave capable of providing high enough data rates, such as, for example an expanded bus interface or a QuadSPI module. Therefore, any compatible graphic stored anywhere on-chip or in an accessible interface can be displayed on the connected TFT LCD panel with no further intervention from the CPU, except to program the DCU4 to fetch and place it. The DCU4 also includes a dedicated memory to store the graphic for its cursor layer.

55.6.2 TFT LCD panel configuration

The nature and timing of the signals required by TFT LCD panels vary greatly between manufacturers. Therefore, the DCU4 allows highly flexible and detailed configuration of these signals.

Timing diagrams for TFT LCD panels are typically divided into a horizontal timing chart and a vertical timing chart. See Figure 55-1929 for details.

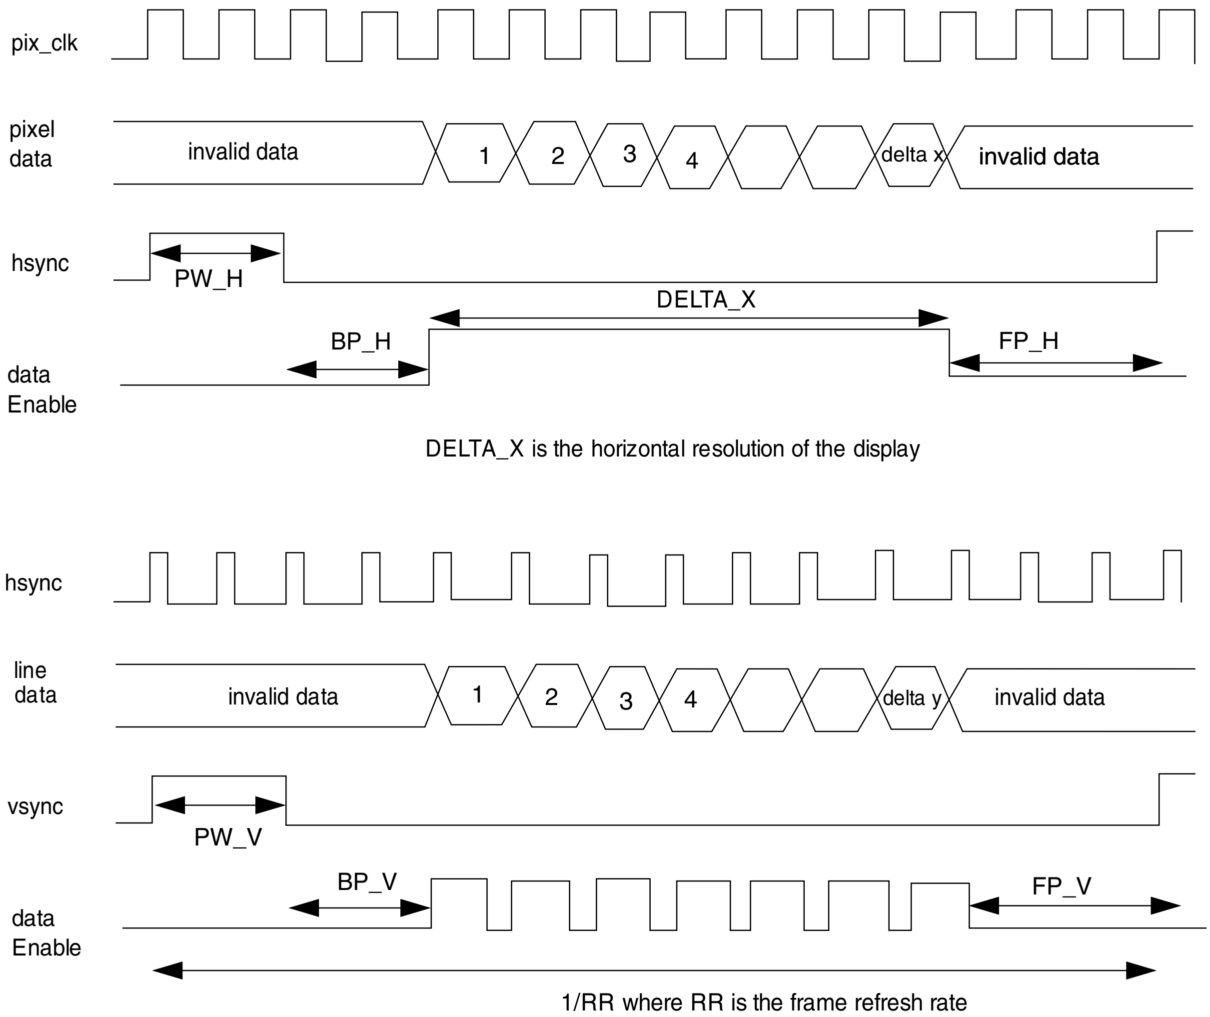

Figure 55-1929. HSYNC and VSYNC timing diagram

The number of pixel data slots in the horizontal timing diagram is defined by the width of the panel. The number of line data slots is defined by the height of the panel. Both of these values are defined in the DISP_SIZE register (DELTA_X, DELTA_Y). The width of the panel must always be defined as a multiple of 16.

The timing of the pixel clock is defined by the DIV_RATIO register and the frequency of the clock supplied to the DCU4.

In addition to defining the number and timing of pixels in each line and the number of lines, it is normal for TFT LCD panel manufacturers to define other timing signals in terms of pixel clock periods or of the number of horizontal lines. The DCU4 also follows this convention.

If the TFT LCD panel requires a horizontal synchronizing signal (HSYNC) and/or a data enable signal, then these can be configured using the fields in the HSYN_PARA register. HSYNC provides a pulse to give the panel notice that the next line of pixel data is about to start, and the data enable signal indicates when that data is present. The PW_H bit field

indicates the width of the HSYNC pulse, in pixel data clock periods. The BP_H bit field defines the delay between the end of the HSYNC pulse and the start of the data enable signal (and pixel data delivery), in pixel clock periods. The FP_H bit field defines the delay between the end of the data enable signal (and pixel data delivery) and the next HSYNC pulse, in pixel clock periods. FP_H and BP_H have minimum values of 1.

If the TFT LCD panel requires a vertical synchronizing signal (VSYNC), then this can be configured using the fields in the VSYN_PARA register. VSYNC provides a pulse to give the panel notice that the next frame of pixel data lines is about to start, and the panel defines delays before and after this pulse, in terms of pixel clock periods. The PW_V bit field indicates the width of the VSYNC pulse in horizontal line periods. The BP_V bit field defines the delay between the end of the VSYNC pulse and the start of the next pixel data (data enable signal), in horizontal line periods. The FP_V bit field defines the delay between the end of the last pixel data (data enable signal) and the next VSYNC pulse, in horizontal line periods. FP_V and BP_V have minimum values of 1.

The polarity of all these signals, including the pixel data itself, may be inverted by using the control bits in the SYN_POL register.

The refresh rate for the panel can be calculated using Table 55-1931 and Pixel Clock calculation below.

$$RR = \frac{\text{pix\_clk}}{(\text{DELTA\_}X+\text{FP\_}H+\text{PW\_}H+\text{BP\_}H)\times(\text{DELTA\_}Y+\text{FP\_}V+\text{PW\_}V+\text{BP\_}V)}$$

where:	pix_clk is the pixel clock
	DELTA_X is the horizontal resolution (in pixels)
	DELTA_Y is the vertical resolution (in pixels)
	FP_H is the hsync front porch pulse width (in pixel clock cycles)
	BP_H is the hsync back porch pulse width (in pixel clock cycles)
	PW_H is the hsync active pulse width (in pixel clock cycles)
	FP_V is the vsync front porch pulse width (in number of horizontal lines)
	BP_V is the vsync back porch pulse width (in number of horizontal lines)
	PW_V is the vsync active pulse width (in number of horizontal lines)

pix_clk = DCU4 Clock / (DIV_RATIO – 1),

where DIV_RATIO is an integer value in the DIV_RATIO register that can range from 1 to 128.

The configuration values in these registers are "locked-in" for the panel when a frame refresh cycle is initiated. For more information about this process see Transfer of DCU Configuration.

55.6.3 DCU4 Mode selection and background color

Once the DCU4 is configured for use with a particular TFT LCD panel, it can be enabled for use. There are five modes to choose from, as shown in the following table.

Table 55-1932. List of DCU operating modes

Mode	DCU_MODE[1:0]	PDI_EN	Description
Off	00	X	DCU4 disabled; the TFT LCD panel is not driven.
Color bar	11	X	DCU4 displays a test pattern consisting of vertical bands of programmable color.
Normal	01	0	DCU4 blends layers and displays result on TFT LCD panel.
PDI normal	01	1	As normal mode, except that the panel timing is defined by the input on the PDI interface, and the background color is replaced by the content provided on the PDI interface.
PDI slave	01	0	The DCU4 synchronizes its timing to an external signal when PDI_SLAVE_MODE is enabled.

The DCU_MODE, PDI_EN and PDI_SLAVE_MODE control bits are in the DCU_MODE register. The DCU4 has an interface enable bit for the TFT LCD panel interface called RASTER_EN, also in the DCU_MODE register. When RASTER_EN is 0, the raster scanning of pixels to the panel is disabled, but the pixel clock continues to run if enabled on the I/O pin.

Color bar mode is intended for testing the interface between the DCU4 and the TFT LCD panel. In this mode, the panel is divided into eight vertical strips of equal width, and the strips display a single color whose RGB value is specified in the COLBAR_1 to COLBAR_8 registers. At reset, the colors are set to black, blue, cyan, green, yellow, red, magenta, and white, where positive logic for the RGB values is assumed. The mode can be used to verify correct connection of the interface to the DCU4 and correct timing configuration of the interface. In this mode, any layer configuration settings are ignored.

In Normal mode, the DCU4 operates according to the timings specified in TFT LCD panel configuration" and displays graphics according to the configuration of its layers. The BGND register sets the RGB color of the background shown when no other layers are present. This background color is included in the layer blending process but, since it is always the background, it does not include any layer blending settings.

In PDI normal mode, the DCU4 adopts the timing provided on the PDI interface and replaces the background color by the pixel data coming from the PDI interface. The timing values set in the DCU4 are ignored in this mode, and the pixel clock and

synchronization signals are taken from the PDI interface and passed to the TFT LCD panel. The content of the panel is a combination of the incoming pixel stream and layers generated by the DCU4.

PDI slave mode allows the DCU4 to synchronize with the external timing signals on the PDI input.

55.6.4 Layer configuration and blending

Users control the graphical content of the TFT panel by manipulating the configuration of elements in the DCU4 called layers. Each layer has control descriptors that define the size, position, memory encoding, blending, and memory location of the graphic to be displayed. The DCU4 provides 64 independent layers that all display graphics with a fixed priority, and this affects how individual pixels are blended when layers overlap. The blending setting on each layer allows the pixels on that layer to be opaque, partially transparent, or fully transparent, which allows them to combine with pixels on other layers that they overlap.

55.6.4.1 Blending priority of layers

The 64 layers available in the DCU4 are each fixed in priority order, with layer 0 being the highest priority, layer 1 being the second highest priority, and so on until layer 63, which is the lowest priority. The priority is used by the DCU4 to define how to blend individual pixels within the layers. For example, if layer 0 is defined as not being blended with other layers and a pixel on layer 0 overlaps a pixel on layer 1 then the pixel on layer 0 will be visible on the panel unchanged by the pixel on layer 1. However, if layer 0 is defined as being partially transparent, then the DCU4 will blend the overlapping pixel such that the result is a combination of the pixel on layer 0 and the pixel on layer 1. It is possible to blend up to six layers at each pixel position.

As there is a maximum number of layers that can blended together, then any pixel on a layer that is lower than the threshold priority will not be included in any blend. If a pixel is on a layer that has the lowest priority in any blending scheme, then the blending settings for that pixel are ignored and the pixel is treated as a background pixel. This means that a lower priority layer may have some pixels completely obscured by those on higher priority layers on one part of the panel, and some other pixels visible or blended on other parts of the panel.

Figure 55-1930 shows how the pixel blend takes place inside the DCU4. The priority of the layers determines at which stage of the blend the pixel enters. Any pixels lower than the threshold priority are ignored and, as can be seen, the blend settings for the lowest

priority pixel is also ignored. The maximum number of pixels in the blend is configured by the BLEND_ITER bit field in the DCU_MODE register. As can be seen in the figure, the blending process is iterative so that six-pixel blending takes more DCU4 clock cycles than five-pixel blending, and three-pixel blending takes more DCU4 clock cycles than two-pixel blending.

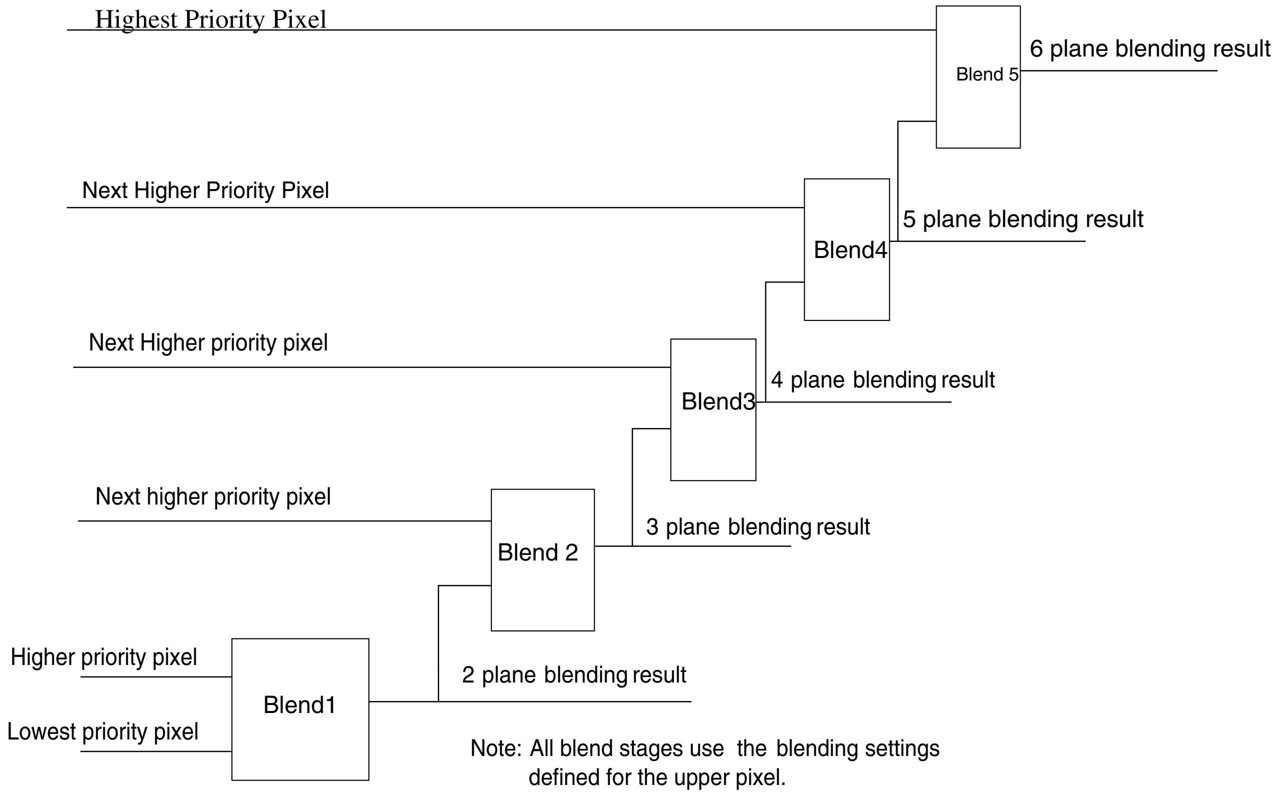

Figure 55-1930. Pixel blending stack

The number of pixels in each blend depends on two factors: The BLEND_ITER setting which defines the maximum and the actual number of layers present at the particular location on the panel. If fewer layers are present than the value in BLEND_ITER then only the number of blend stages required will occur. If more layers are present than the value in BLEND_ITER then the pixels below the lowest priority pixel are ignored. Note that the blend stack always operates from the lowest to highest such that a two layer blend will always use FIFO CH1 and CH2 to produce the 2 pixel blending result whereas a five layer blend will use CH1, CH2, CH3, CH4 and CH5 to produce the 5 pixel blending result.

This priority concept is illustrated in Figure 55-1931 and Figure 55-1932. In this case, there are five layers enabled, and each contains a graphic that is a solid rectangular block of a single color. The size and shape of each layer is different. The background color of the panel is set to grey and layers have been placed such that they overlap each other.

Figure 55-1931 shows the individual source graphics and the case where no layer has any blending enabled. Here, the highest priority layer (in this case layer 0) is fully visible. Layer 1 is visible where layer 0 does not overlap it. Layer 2 is visible where layer 1 does not overlap it. Layer 3 is overlapped by layers 0 and 1 and so is only partially visible. Layer 4 is partially obscured by all of the other layers. Note that layer 4 is higher priority than the background color.

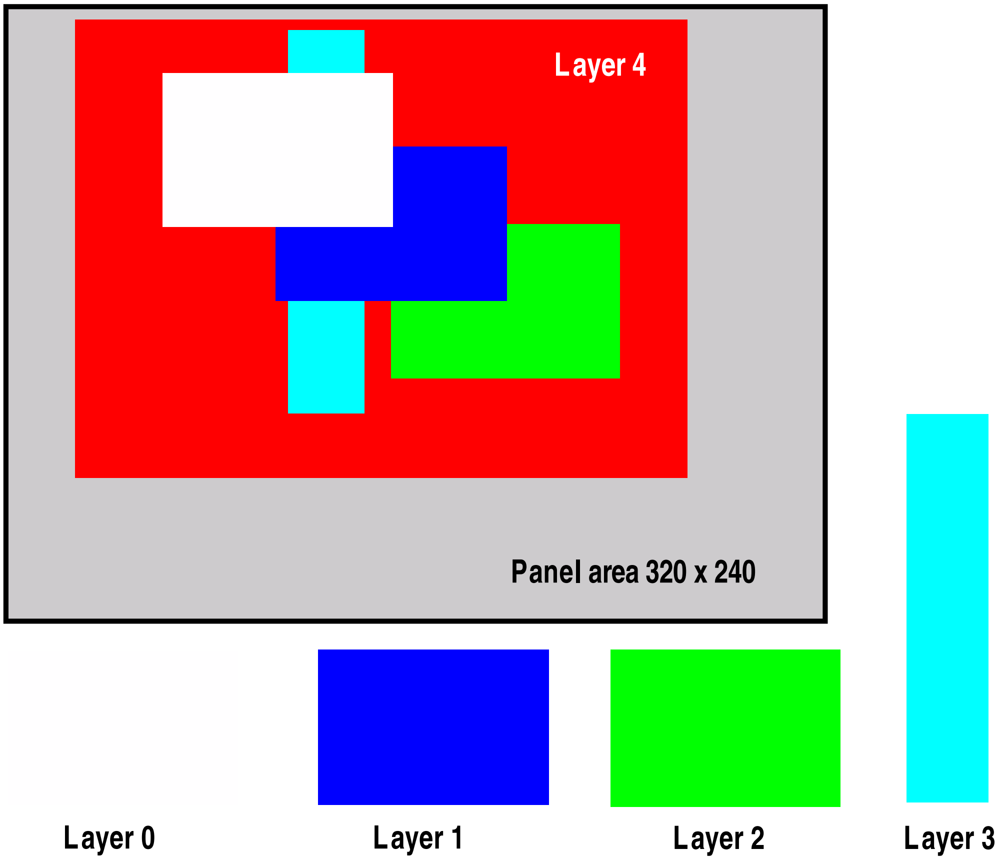

Figure 55-1931. Example of layer placement with no blending

Figure 55-1932 shows the same layer configuration except that, in this case, the layers have been made 50% transparent and the depth of the pixel blend is set to 3. The pixels in layer 0 are now blended with pixels in the underlying layers. In particular, note region A where layer 0 is blended with layer 4 and the background color. This blending effect is repeated across all of the layers; however, note the pixels in region B. In this region the pixels from layer 0 are blended with those on layer 1 and layer 2; however, the pixels from layer 4 and the background color are not included in this blend. This is because the DCU4 is configured to blend three layers only, and so the blend setting for layer 2 is ignored for those pixels in region B.

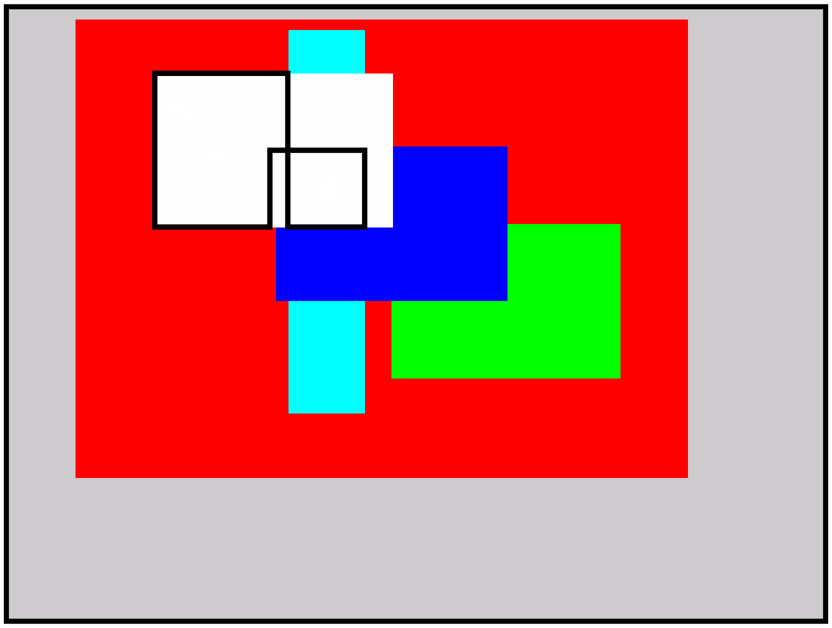

Figure 55-1932. Example of layer placement with 3-layer blending

All blending is performed using full 8-bits-per-component colors. The DCU4 automatically performs a color promotion on source data that is stored in less than RGB888 color.

55.6.4.2 Transfer of DCU Configuration

The configuration of the DCU occurs in two stages. Firstly the configuration values are written into the appropriate register by the user software. Secondly, these values are transferred into the frame timing logic for use on the next frame refresh. This means that the values written into the registers do not take effect until the transfer completes. Similarly, error conditions will not be detected until the transfer occurs and so error flags will not be set until the transfer is complete. Refer to the register descriptions for details of which registers require this transfer operation.

The transfer itself always occurs at a fixed time in relation to the vertical blanking period. The time at which the control descriptors are updated and ready to transfer is under user control and there are two control bits in the UPDATE_MODE register that determine how the DCU behaves. The READREG bit causes a single transfer to begin at the next frame blanking period. This bit is cleared when the transfer is complete. The MODE bit forces the transfer to occur on every frame blanking period. This means that any changes to the affected registers must be complete before the transfer is ready to begin otherwise coherency issues can occur. The DCU provides a status flag called PROG_END bit in the

INT_STATUS register which is asserted when the transfer is beginning and a status flag called LYR_TRANS_FINISH which indicates when the transfer is complete. Both of these status flags can generate an interrupt.

Changes to register contents before the transfer is complete may be copied as part of the transfer.

NOTE

Every transfer must be performed using the READREG bit until the DCU_MODE[DCU_MODE] bit field is set to non-zero. All subsequent transfers may be performed using either the READREG or the MODE bit method.

55.6.4.3 Control Descriptors

The control descriptor for each layer consists of nine registers, and all 64 control descriptors have common features that allow the display and blending of a graphic in the frame. In addition, the top two layers (0 and1) have additional control bits for the safety mode. The top and bottom eight layers (0 to 7 and 56 to 63) also have support for tile mode.

The control descriptors contain the configuration that will be used for a future frame. The current frame configuration will remain the same until all of the control descriptor contents are updated by the user and subsequently transferred to the frame timing logic. Once this transfer is complete the control descriptors can be modified for the next frame.

55.6.4.4 Layer size and positioning

The size of each layer is defined by register 1 in the control descriptor for the layer (CTRLDESCLn_1, where n is the layer number). The register contains two bit fields, HEIGHT and WIDTH, which determine the size and shape of the layer. Both fields are expressed in terms of the number of pixels in each dimension.

The HEIGHT bit field may take any value.

The WIDTH field has a restriction on the value it can take, depending on the data format of the graphic specified by the layer. This field must always be an integer multiple of the number of pixels that are represented by a 32-bit word except in the special case of 1 bit per pixel where the multiple is 16. The data format can range from 1 bit per pixel to 32 bits per pixel and so there is a range of multiples from 1 to 32. Table 55-1933 shows the multiples for the WIDTH bit field and some correct values.

Table 55-1933. Example of WIDTH multiples for different graphic data formats

Data format	WIDTH multiples	Example values
1 bpp	16	16, 32, 48, 64, …
2 bpp	16	16, 32, 48, 64, …
4 bpp	8	8, 16, 24, 32, …
8 bpp	4	4, 8, 12, 16, …
16 bpp	2	2, 4, 6, 8, …
24 bpp	4 (= 3 whole 32-bit words)	4, 8, 12, 16
32 bpp	1	1, 2, 3, 4, …
YUV422	4	4, 8, 12, 16, …

If the WIDTH bit field is set to an invalid multiple, then the layer configuration is invalid, the layer cannot be made visible, and an error flag is set in the layer parameter error register (PARR_ERR_STATUS1 and PARR_ERR_STATUS2).

The position of each layer on the panel is defined by register 2 in the control descriptor for the layer (CTRLDESCLn_2, where n is the layer number). The register contains two bit fields, POSY and POSX, which determine the location of the upper left pixel of the layer in the x and y axes. Both fields are expressed in terms of the number of pixels in each axis.

There are no restrictions on layer placement. Any layer can be placed and moved to any panel position. If a layer is placed so that pixels would appear beyond the dimensions of the panel, then the DCU4 displays the pixels on the panel and ignores the pixels off the panel.

55.6.4.5 Graphics and data format

The memory location of the graphic that is displayed on the layer is defined by register 3 in the control descriptor for the layer (CTRLDESCLn_3, where n is the layer number). This 32-bit value can contain the address of any memory location in the memory map of the MCU.

The format of the data that describes the graphic is defined by the BPP bit field in register 4 in the control descriptor for the layer (CTRLDESCLn_4, where n is the layer number). This value also influences the range of values for the width of the layer (see Layer size and positioning"). By choosing an appropriate format, it is possible to optimize the memory required by the graphics in use.

There are five modes where the RGB values of the pixels are stored directly in the graphic. In these modes, the DCU4 treats the data as describing a true RGB color. The modes are:

- ARGB8888, where the data defines 8-bit values for the red, green, blue, and alpha components of the image. This blends as ARGB, however, in this format the order of the bytes is reversed compared to other formats.
- RGB888, where the data defines 8-bit values for the red, green, and blue components of the image.
- RGB565 where the data defines 5-bit values for the red and blue components, and 6-bit values for the green component of the image.
- ARGB1555 where the data defines 5-bit values for the red, green, and blue components, and a 1-bit value for the alpha channel of the image.
- ARGB4444, where the data defines 4-bit values for the red, green, blue, and alpha components of the image.

The three 16-bit formats (RGB565, ARGB1555, and ARGB4444) are promoted to full 8 bit per component format by shifting the bits left so that the MSB of the component in the 16-bit format becomes the MSB of the 24/32 bpp (bit per pixel) format, and the LSB is filled with the value of the MSBs. For example, an RGB565 value of 10000:010000:11011 becomes 10000100:01000001:11011110. An RGB4444 value of 1010:0011:1100:0101 becomes 10101010:00110011:11001100:01010101. An RGB1555 value of 1:10100:01000:11011 becomes 11111111:10100101:01000010:11011110.

There are five indexed color formats (1/2/4/8 bpp & APAL8) where the data in the graphic does not define the RGB color to display. Instead, the data defines the entry in a color look-up table (CLUT) that contains a palette of ARGB colors. The maximum number of colors in the CLUT is defined by the size of the data stored in the graphic. For 1 bpp graphics, there is a maximum of two colors in the CLUT. For 2 bpp, there is a maximum of four colors. For 4 bpp and 8 bpp data, the maximums are 16 and 256 colors, respectively. In APAL8 mode(16 bpp), the upper 8 bits define the alpha component of the pixel and the lower 8 bits define the offset in the CLUT (the alpha component in the CLUT color is ignored).

The address of the first value in the CLUT is defined in the LUOFFS bit field of register 4 and the CLUT is the RAM block dedicated to the DCU4 which is described in CLUT/Tile RAM". Since the RGB values stored in the CLUT are 32-bit RGB, there is no need for further adjustment before blending.

The DCU4 also supports graphics encoded using luminance and chrominance format. This format is generically known as YUV and stores the luminance (brightness, Y) of a pixel separate from its chrominance (color information, U and V). This format is widely used by cameras and is supported by the PDI for direct video in as well as the DCU4 when stored in memory for display on a layer. The specific implementation used by the DCU4 is more accurately described as YCbCr422 which uses twice as many bits to describe the luminance as to describe the blue (Cb) and red (Cr) difference of the chrominance.

The DCU4 takes these pixels and converts them to RGB format using equations configured using its LYR_LUMA_COMP, LYR_CHROMA_RED, LYR_CHROMA_GREEN, and LYR_CHROMA_BLUE registers. The YCbCr format specifies a common chroma setting for two pixels; however, it is possible to interpolate the chroma for the pixels rather than setting both to the same value. This feature is enabled by the LYR_INTPOL_EN[EN] field. Due to the additional conversion step required, the DCU4 is able to blend a maximum of one layer encoded in YCbCr for each pixel. See “PDI YCbCr mode and DCU4 YCbCr color format.

There are four additional modes defined by the BPP bit field. These configure the graphic in transparency mode and luminance mode (see Transparency mode and blending" and Luminance mode" respectively).

There is a set storage format for each data format provided by the DCU4. These formats can be seen in the following tables.

Table 55-1934. Data Layout for ARGB8888

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	A0	R0	G0	B0	A1	R1	G1	B1
0x08	A2	R2	G2	B2	A3	R3	G3	B3

In the following table, the YCbCr422 format encodes chroma information across two pixels. Therefore, the chroma values apply to the even pixel denoted in the table and its adjacent odd pixel.

Table 55-1935. Data layout for YCbCr422 format

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	Y1	Cr0	Y0	Cb0	Y3	Cr2	Y2	Cb2
0x08	Y5	Cr4	Y4	Cb4	Y7	Cr6	Y6	Cb6

Table 55-1936. Data Layout for 24 bpp

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]
0x00	B1	R0	G0	B0	G2	B2	R1	G1
0x08	R3	G3	B3	R2	B5	R4	G4	B4

For 16 bpp, data expected is in the form of RGB565, ARGB1555 or ARGB4444, or APAL8.

Table 55-1937. Generic data layout for 16 bpp

Address offset	[31:24]	[23:16]	[15:8]	[7:0]	[31:24]	[23:16]	[15:8]	[7:0]

The DCU4 includes a flag that indicates when it has completed fetching graphics from memory for the current frame refresh. If required, this flag (DMA_TRANS_FINISH in the INT_STATUS register) can be used to determine when changes can be made to the source graphic content.

55.6.4.6 Alpha and Chroma-key blending

The blending configuration of each layer is defined by the BB, AB, and TRANS bit fields in register 4 in the control descriptor for the layer (CTRLDESCLn_4, where n is the layer number). The pixels affected by the blending configuration can be further selected by registers 5 and 6 in the control descriptor (CTRLDESCLn_4 and CTRLDESCLn_5). Depending on the priority and placement of the layer (see Blending priority of layers"), these bit fields and registers define how pixels from different layers are blended together.

The AB and BB bit fields define whether blending is active and whether the whole graphic or a selected portion is blended. Registers 5 and 6 specify the range of RGB colors that define the selected pixels. The TRANS bit field defines the transparency of the selected pixels.

The BB bit field defines whether the whole graphic, or only certain pixels, should be blended. When this bit is set, pixels that have an RGB value that falls into the range defined by registers 5 and 6 are considered to be selected and treated differently to the non-selected pixels in the graphic. This is a process known as chroma-keying since it is the color of the pixel that defines the selection. The selected pixels must be within the range defined by each color component of registers 5 and 6. See Table 55-1946 for examples of pixels that are selected and not selected when the given range is defined as 0x0080C0 to 0x0FB0FF.

Table 55-1946. Example of how chroma-key range selects pixels

Source pixel	Red 00–0F	Green 80–B0	Blue C0–FF	Comment
0x000000	P	X	X	Not selected
0x08C0C0	P	X	P	Not selected
0x08A0C0	P	P	P	Pixel is selected

The AB bit field defines how any selected and non-selected pixels are blended. By combining this control with the BB bit field it is possible to define 11 unique ways of blending the pixels on a layer dependent on the type of layer. Depending on the configuration defined by the AB and BB bit fields, the TRANS bit field combines the two pixels in every blend stage using the alpha value of the upper pixel (which has the effect of making this pixel more or less transparent and revealing more or less of the lower pixel).

The result of each blend stage is calculated for all three color components as shown in Figure 55-1932.

$$A = (\mathrm{BGPixel} * (255 - \mathrm{alpha})) + (\mathrm{FGPixel} * \mathrm{alpha})$$

The result of the calculation must then be divided by 255 to normalize the result. This calculation is performed as follows:

1. First Division output_val = A + (A >> 8)
2. Rounding off first addition & division if (((A>>7) & 0x1) == 0x1) output_val ++
3. Second Division with rounding output_val = output_val >>7; if ((output_val & 0x1) == 0x1)) output_val = output_val + 0x2; output_val = output_val >> 1

The blend can apply to pixels with no alpha channel (RGB) or with an alpha channel (ARGB) in different ways.

Table 55-1947 defines how the settings of the BB and AB bit fields affect the pixels in the layer; RGB modes are 1 bpp, 2 bpp, 4 bpp, 8 bpp, RGB565, and RGB888; ARGB modes are ARGB1555, ARGB4444, and BGRA8888.

Table 55-1947. Blend options for BB and AB configurations

Case	BB	AB[1:0]	Mode	Function
1	0	00	RGB	No blending, underlying pixels are obscured
2	1	00	RGB	Selected pixels are completely removed
3	0	01	RGB	The value in TRANS becomes the alpha channel of all pixels on the layer
4	1	01	RGB	The value in TRANS becomes the alpha channel of the selected pixels on the layer
5	0	10	RGB	Same as case 3
6	1	10	RGB	Selected pixels are completely removed and the value in TRANS becomes the alpha channel of the non-selected pixels on the layer
7	0	11	RGB	Reserved
8	1	11	RGB	Reserved
9	0	00	ARGB	No blending, pixel alpha is ignored and underlying pixels are obscured
10	1	00	ARGB	Selected pixels are completely removed, pixel alpha is ignored
11	0	01	ARGB	Pixel alpha is used to blend layer with underlying pixels. Value in TRANS is ignored.
12	1	01	ARGB	Uses the pixel alpha of the selected pixels only to blend layer with underlying pixels. Value in TRANS is ignored.
13	0	10	ARGB	The value in TRANS is multiplied with the pixel alpha value and the resultant alpha is used to blend all the pixels
14	1	10	ARGB	Selected pixels are completely removed, the value in TRANS is multiplied with the pixel alpha value and the resultant alpha is used to blend the non-selected pixels on the layer
15	0	11	ARGB	Reserved
16	1	11	ARGB	Reserved

Figure 55-1933 to Figure 55-1941 illustrate the effect of the cases identified in Table 55-1947. In all cases there is a single active layer and a white background color.

55.6.4.7 Transparency mode and blending

Transparency mode is a special case for the graphic data format and is defined by the BPP bit field in register 4 in the control descriptor for the layer (CTRLDESCLn_4, where n is the layer number). This value also influences the range of values for the width of the layer (see Layer size and positioning"). By choosing an appropriate format, it is possible to optimize the memory required by the graphics in use.

In transparency mode, the source graphic does not contain any direct or indexed color information. Instead, the graphic data represents the alpha channel of the graphic. The DCU4 creates the final graphic by pre-blending a foreground color and background color using the alpha value of each pixel. The result of this pre-blend can then be blended with pixels on other layers using the normal blending process. Each layer has dedicated registers to contain the foreground and background colors for this mode within the control descriptor. These are registers CTRLDESCLn_8 and CTRLDESCLn_9, where n is the layer number. See Figure 11-76.

Transparency mode is typically used when a graphic must blend smoothly into the underlying layers, but where a rich color palette is not required. Examples include text where this mode allows the text to blend smoothly with any background — this is known as anti-aliasing.

There are two transparency modes available: 4 bpp and 8 bpp. The 4 bit data is translated to 8 bit by concatenating the 4 bits.The result of the pre-blend can be treated as an RGB888 graphic and blended in a similar way to previously described, or it can be treated as a special case of ARGB with only the foreground color visible in the final blend. Table 55-1948 describes the blend options for transparency mode.

Table 55-1948. Blend options for transparency mode

Case	BB	AB[1:0]	Mode	Function
1	0	00	Transparency	No blending, underlying pixels are obscured
2	1	00	Transparency	Reserved
3	0	01	Transparency	The value in TRANS becomes the alpha channel of all pixels on the layer
4	1	01	Transparency	The value in TRANS becomes the alpha channel of the selected pixels on the layer
5	0	10	Transparency	Same as case 3
6	1	10	Transparency	Background color is ignored, selected pixels are completely removed, the value in TRANS is multiplied with the graphic data value (alpha) and the resultant alpha is used to blend the non-selected pixels on the layer
7	0	11	Transparency	Reserved
8	1	11	Transparency	Reserved

Figure 55-1942 –Figure 55-1945 illustrate the effect of the cases identified in Table 55-1948. In all cases there is a single active transparency layer and a white background color.

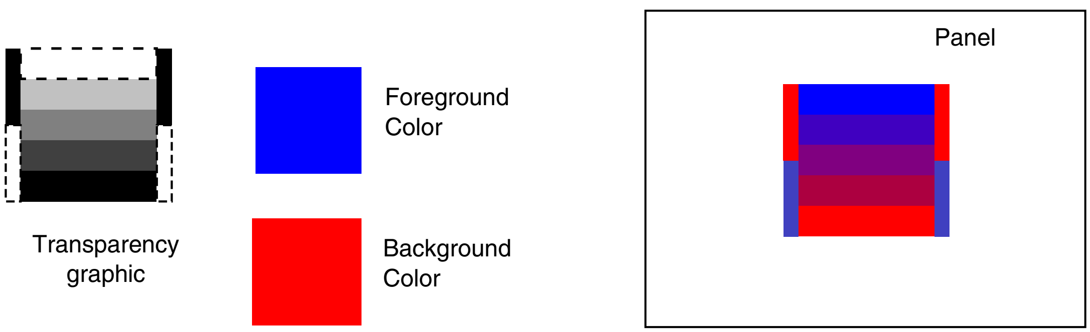

Figure 55-1942. Case 1 example (no blend)

Alpha = 0 Chroma range = 0 Alpha = 50% Chroma range = 0

Figure 55-1945. Case 6 example (only foreground color blended)

55.6.4.8 Luminance mode

Luminance mode is a special case for the graphic data format and is defined by the BPP bit field in register 4 in the control descriptor for the layer (CTRLDESCLn_4, where n is the layer number). This value also influences the range of values for the width of the layer (see Layer size and positioning"). By choosing an appropriate format, it is possible to optimize the memory required by the graphics in use.

In luminance mode, the data in the source graphic does not contain any direct or indexed color information or alpha information. The data values in a layer in luminance mode modify the values of the pixels on underlying layers only. There are two luminance modes available: 4 bpp and 8 bpp. In both cases, the data values behave as signed integers that are added to each component of the underlying pixel. The 4 bpp mode is left-shifted with the 4 bits concatenated to form a signed 8 bpp integer. The results of the addition are prevented from overflowing, so that any result greater than 0xFF is set to 0xFF and any result less than 0x00 is set to 0x00.

The result of a blend with a luminance layer is that the intensity of the underlying pixel's color will be increased or decreased. In this way, luminance mode can be used to highlight or dim pixels on the panel without having to modify the source graphic data. Table 55-1949 describes the effect of luminance blends on an underlying pixel.

Table 55-1949. Example of a blend with a luminance mode layer

Pixel value	Luminance value	Resultant pixel
0xFF8040	0x40	0xFFC080
0xFF8040	0xC0	0x3F0000

55.6.4.9 Tile mode

Tile mode is a special case for the layer and is enabled by the TILE_EN bit field in register 4 in the control descriptor for the layer (CTRLDESCLn_4, where n is the layer number). Tile mode is only available on layers 0 to 7 and 56 to 63.

In this mode the layer size register (CTRLDESCLn_1, where n is the layer number) defines the size of the layer; however, the size of the graphic is defined in control register 7 (CTRLDESCLn_7, where n is the 64layer number). The size of the graphic must be less than or equal to the size of the layer. When tiled mode is enabled, the graphic is repeated horizontally and vertically until it fills the whole layer. The horizontal size of the tile is defined by the TILE_HOR_SIZE bit field and is restricted to be a multiple of 16 pixels. The vertical size of the tile is defined by the TILE_VER_SIZE bit field.

The graphic data for the Tile Mode can be fetched either from the system memory or from the internal CLUT/Tile memory. This is defined by the DATA_SEL bit field in register 4 in the control descriptor for the layer. If the graphic is fetched from CLUT/tile memory then it must be in RGB888 format. Otherwise the graphic can be in any previously described data format. See Figure 55-1946 for an example of a layer in tile mode.

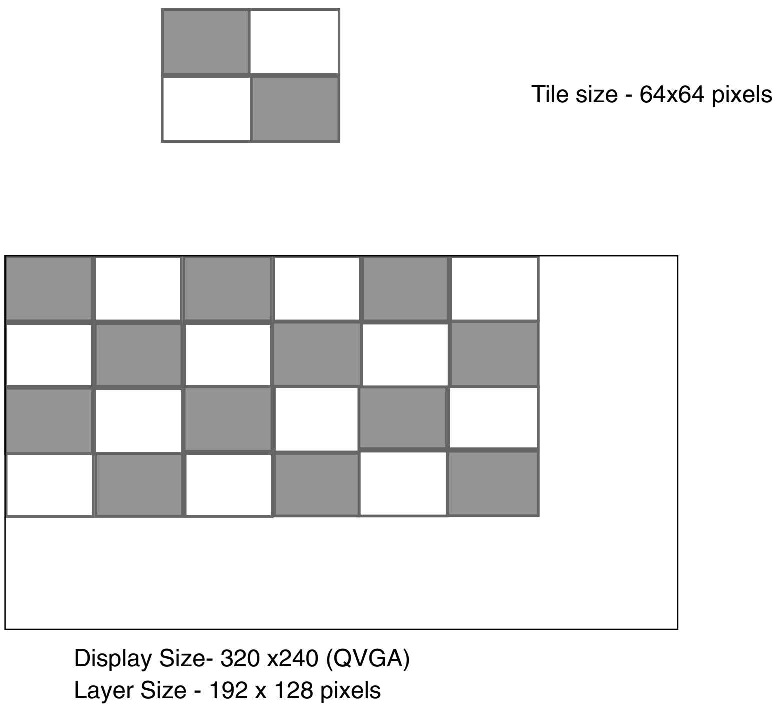

Figure 55-1946. Tile Mode

55.6.5 Hardware cursor

In addition to the 64 layers, the DCU4 also provides a special layer intended for use as a cursor. This cursor operates in 1 bpp mode and includes its own RAM area to store the graphic. The cursor may be placed at any location on the panel and includes an automatic blink option. The hardware cursor is configured using a dedicated control descriptor.

The size of the cursor is defined by register 1 in the control descriptor for the cursor (CTRLDESCCURSOR_1). The register contains two bit fields, HEIGHT and WIDTH, which determine the size and shape of the layer. Both fields are expressed in terms of the number of pixels in each dimension. The HEIGHT is limited to a maximum of 256 pixels, and the total number of pixels cannot exceed the number of bits in the cursor RAM (8192 bits).

Bits in the cursor RAM that are 0 become transparent on the panel. Bits that are 1 become fully opaque in the color defined in register 3 in the control descriptor for the cursor (CTRLDESCCURSOR_3). The DEFAULT_CURSOR_COLOR bit field is in RGB888 format.

There are restrictions on the arrangement of bits in the cursor RAM depending on how the HEIGHT and WIDTH bit fields are configured.

- When the cursor width is an integer multiple of 32 bits, the pixels in each row roll from one word in the RAM to the next one. The rightmost bit in the first word in the RAM is the t op leftmost pixel on the display. The leftmost bit in the word represents a pixel that is adjacent to the rightmost bit in the next word (in the same row). The leftmost pixel on the next row is the rightmost bit in the first word after n words that describe the first row.
- When the width of the cursor is greater than 32 bits but not an integer multiple of 32, the pixels in each row roll from one word into the next one such that the rightmost bit in the first word of the row is the leftmost bit on the display. In the final word of the row there are unused bits.

The position of the cursor on the panel is defined by register 2 in the control descriptor for the cursor (CTRLDESCCURSOR _2). The register contains two bit fields, POSY and POSX, which determine the location of the upper left pixel of the cursor in the x and y axes. Both fields are expressed in terms of the number of pixels in each axis. Placing the cursor beyond the panel area is not allowed.

The cursor can be configured to blink at a particular rate when it is enabled. The EN_BLINK, HWC_BLINK_ON, and HWC_BLINK_OFF bit fields define the blink behavior. These are in register 4 in the control descriptor for the cursor (CTRLDESCCURSOR_4). EN_BLINK enables blinking. The blinking time is based on the frame rate, and the on and off times are independently configurable. HWC_BLINK_ON configures the number of frame refresh cycles for which the cursor is

visible. HWC_BLINK_OFF configures the number of frame refresh cycles for which the cursor is not visible. For a frame refresh rate of 64 Hz, the HWC_BLINK_ON and HWC_BLINK_OFF counters give a range of on/off times up to 4 seconds.

The cursor is enabled by setting the CUR_EN bit field in register 3 in the control descriptor for the cursor (CTRLDESCCURSOR_3).

If the DCU4 detects an invalid configuration in the cursor control descriptor, then the cursor configuration is invalid and it cannot be made visible. In addition, the error flag HWC_ERR is set in the layer parameter error register (PARR_ERR_STATUS3).

The cursor RAM may be written at any time when the TFT LCD panel is not being driven with data. This means that the RAM can be modified when the DCU4 is not enabled and during the vertical blanking period.

55.6.6 CLUT/Tile RAM

The internal tile memory and color look up table (CLUT) memory share a common block of RAM internal to the DCU4. Color information in this RAM is always stored as aligned 32-bit words where the most-significant byte is the alpha component, the next byte contains the red component, the next the green component and the least significant byte the blue component (0xAARRGGBB).

This memory block can be used to store either color look-up tables or graphics for use as a tile on a layer. The content of the RAM at a specific address is defined by the control descriptor of a layer. The LUOFFS bit field in the layer control descriptor defines the starting address of the area, and the BPP and TILE_EN bit fields define what type of use the RAM area has.

In Figure 55-1947 three areas of the RAM are defined for different purposes. Area A is used by layer 1 as a CLUT for its 4 bpp graphic. Area B is use by layer 5 as a store for its tile graphic. Area C is used by layers 2, 7, and 9 as a CLUT for their 8 bpp graphics.

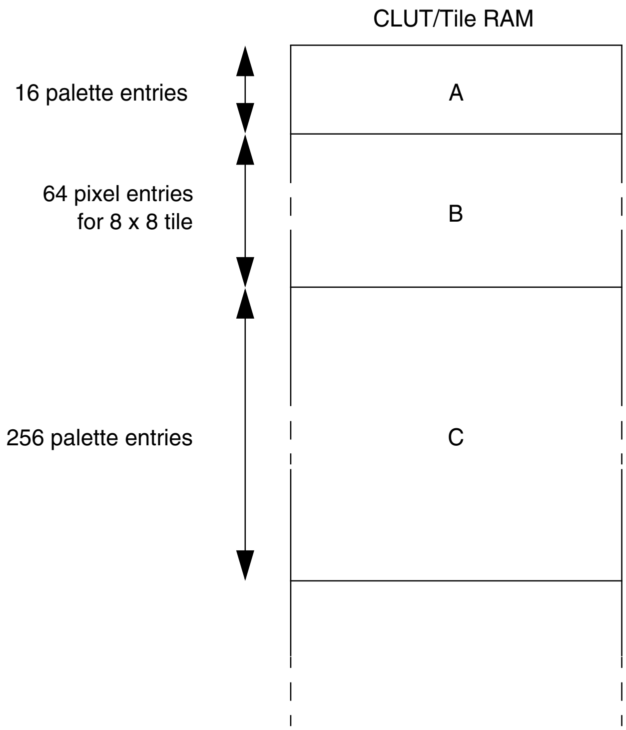

Figure 55-1947. An example of use for the CLUT/Tile RAM

The CLUT/Tile RAM is mapped in the DCU4 32K memory space from address 0x2000 to 0x3FFF. This gives 2048 entries, which provides up to eight full CLUTs for 8 bpp layers.

The CLUT/Tile RAM may be written at any time when the TFT LCD panel is not being driven with data. This means that the RAM can be modified when the DCU4 is not enabled and during the vertical blanking period.

55.6.7 Gamma correction

The gamma table allows the user to define an arbitrary transfer function at the output of each color component. The function (Gamma correction) is applied to each pixel after all blending is complete and before the data is driven to the TFT LCD panel. Gamma correction is optional and can be used to adjust the color output values to match the gamut of a particular TFT LCD panel, or to perform data inversion or data length reduction on each component.

$$\mathrm{output\_color\_component} = \mathrm{gamma\_table}[\mathrm{input\_color\_component}]$$

The table is arranged as three separate memory blocks within the DCU4 memory map; one for each of the three color components. Each memory block has one entry for every possible 8-bit value and the entries are stored at 32-bit aligned addresses. This means that the upper 24 bits are not used while reading/writing the gamma memories. See Figure 55-1948 for details of the memory arrangement.

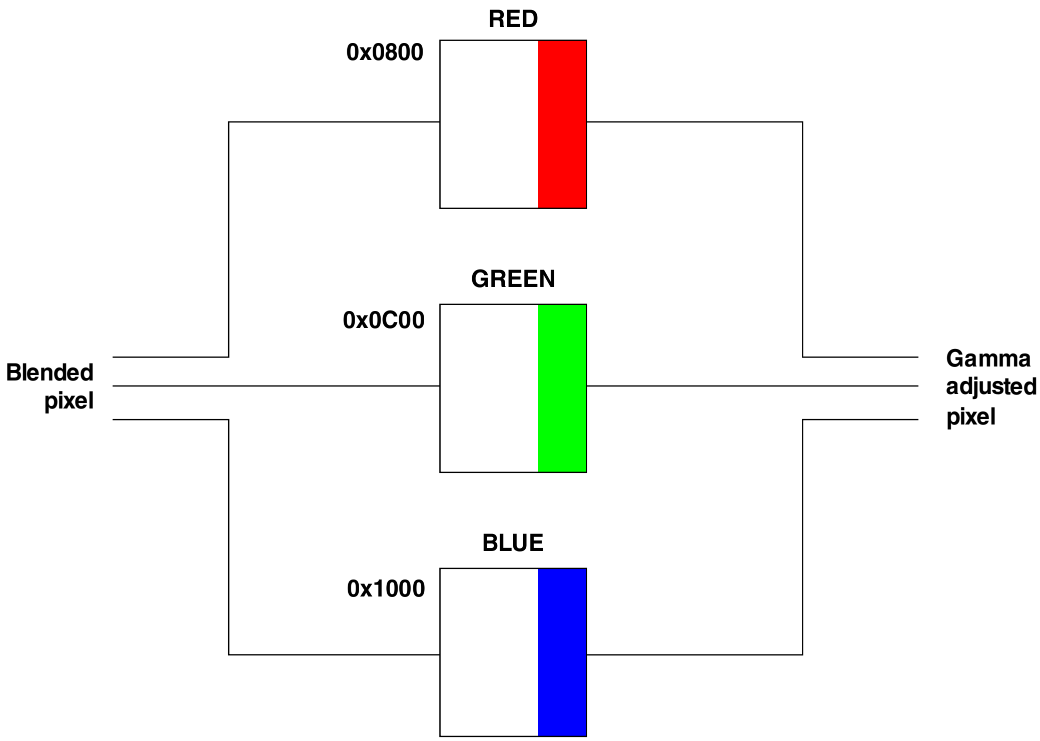

Figure 55-1948. Gamma Correction Table Organization

The gamma table can only be read or written when the DCU4 is not enabled or during the vertical blanking period.

55.6.8 Temporal Dithering

This is a technique that allows the emulation of a color resolution higher than the resolution supported by the display. It is done by changing the intensity values over time sent to the display. The averaging done by the human eye gives the impression of the intensity of such alternating pixels as an interim value between the two supported intensity values. Temporal dithering is enabled by the DCU_MODE[DITHER_EN] bit.

The key features of the dithering block are:

- Temporal dithering increases the optically perceived depth of a limited TFT display.
- Supports display with 5-8 bits resolution per color component.
- Independent dither control parameters per color component.
- Support for safety mode.

Temporal dithering is enabled and controlled by the EN_DITHER, ADDB, ADDG, and ADDR bits in the DCU_MODE register. The ADDx fields are each 2 bits wide and select how many bits to add to each color component. The typical setting is 8 minus the number of bits in each component required by the display.

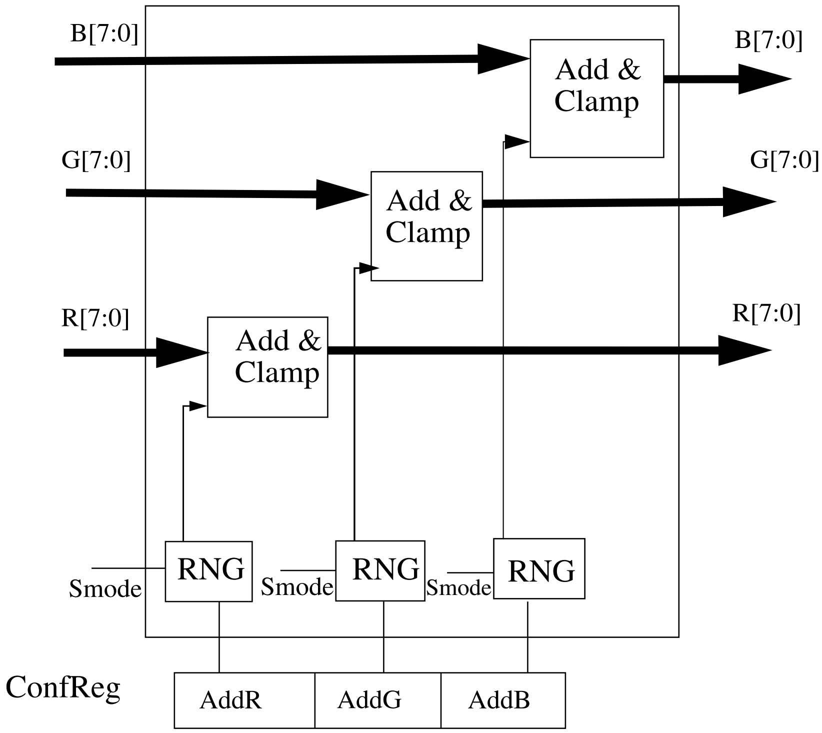

Figure 55-1949. Dithering block diagram

The Random Number Generator (RNG) provides a random number of up to 3 bits. The number of bits provided is selected by the values of each component's ADDx field.

When pixels from a safety layer are encountered the RNG output is forced to 0 which effectively disables the temporal dithering block and these pi xels are passed to the display unmodified.

The Add & Clamp block adds the eight bit pixel value to the thr ee bit number generated by the RNG. The result is then clamped to the range of 0..255.

55.6.9 Special DDR Mode

Special DDR mode is a special configuration that optimizes the use of an SDRAM memory by the DCU4 by forcing the DCU4 to fetch data in optimal chunks. In this special mode only the six highest priority layers (0:5) are available in the DCU4. This mode is enabled using the DCU_MODE[DDR_MODE] bit.

When this mode is enabled the DCU3 will fetch data in 32-byte chunks if the layer is encoded in 8, 16 or 32 bpp formats, thus optimizing the SDRAM throughput. Any layers in 1, 2, 4 or 24 bpp formats will be fetched using normal access thus they will not benefit from any optimization and may disrupt optimal access for any 8-, 16- and 32-bit formatted layers if both are in the SDRAM. Therefore it is highly recommended to store any 1, 2, 4 or 24 bpp layers in non-SDRAM memory such as on-chip SRAM.

Depending on the layer configuration in use this mode may also benefit other synchronous memory interfaces such as QuadSPI.

This mode only permits operation in four-layer blend mode, therefore, the DCU_MODE[BLEND_ITER] field must be set to 4.

55.6.10 Run Length Encoding (RLE) Mode

RLE mode is available on the all the layers and allows the DCU5 to load RLE compressed data from memory and directly decode it for use on the panel. The mode is enabled using the RLE_EN bit in the control descriptor 4 register CTRLDESCLn_4. This mode is only available when Special DDR mode is enabled and can only be used on layers equal to a number of rle layers at a time . Maximum value of number of rle layers can be 6. In addition the mode only supports 8 bpp, 16 bpp (RGB565, ARGB1555, ARGB4444, APAL8), 24 bpp and 32 bpp BGRA8888 formats.

When enabled, the DCU5 fetches encoded data on start of arbitration and provides the decompressed data according to the new arbitration scheme to the normal DCU blend process.

The following figure shows the dataflow for the RLE decoded data.

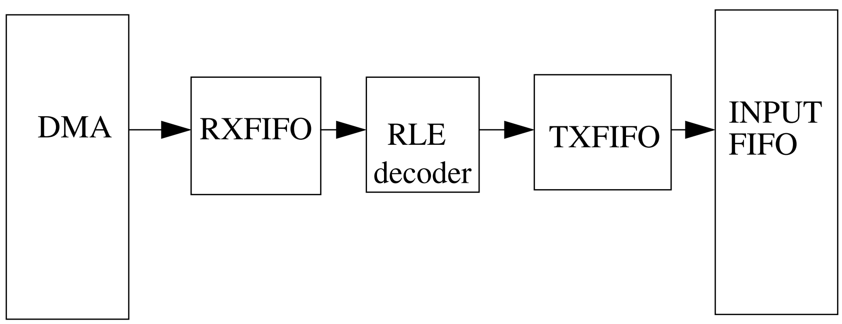

Figure 55-1950. RLE Decoding in DCU5

The decoded data is read by the input FIFO once at l east 8 bytes are available in the TXFIFO. The size of RXFIFO is 64x8 bits while the size of TXFIFO is 16x8 bits.

If more than the number of rle layers have RLE_EN set, then the error flag RLE_ERR is asserted.

55.6.10.1 RLE Decoding Scheme

Before enabling an RLE encoded layer configure the COMP_IMSIZE register with the size of the compressed image. The decoder expects to read COMP_IMSIZE bytes from the image and produce from that the number of pixels specified in the layer Control Descriptor 11 register.

The format of RLE encoded layers is as follows:

- The first data byte read at the image address (Layer Control Descriptor 3) is a command byte (CMD[7:0]).
- The ms bit (CMD[7]) indicates if the following bytes are raw or compressed pixels. One pixel can be 8-bit, 16-bit, 24-bit or 32-bit wide, depending on the BPP bit field in the Layer Control Descriptor 4 register.
- The remaining 7 command bits (CMD[6:0]) specify the number of raw or compressed pixels that follow the command byte. This count is offset by 1 such that a value of 0 means one pixel follows.
- For compressed pixels (CMD[7] = 1), only one pixel follows the command byte. This pixel is repeated count+1 times on the layer. The pixel size may be 8, 16, 24 and 32 bits.
- For raw pixels (CMD[7] = 0) count + 1 pixels follow the command byte and these are included on the layer as is. The pixel size may be 8, 16, 24 and 32 bits.
- If there is more data to decode, a new command follows after CMD+(1*{Pixel width}) bytes. This encoding is repeated until the whole image is decoded.

55.7 Timing, Error and Interrupt Management

The DCU4 can detect and raise status and error flags when the status of the system changes and when configuration or operational errors are detected.

55.7.1 Synchronizing to panel frame rate

Since the DCU4 fetches data directly from memory independently of the CPU, there is the possibility that changes to the DCU4 layer configuration or content can create incoherent content on the panel. To help avoid this situation there are five timing control flags that define when the DCU4 recognizes and locks changes to its configuration. These can be used to manage changes to control descriptors, CLUT or tile memory, or source graphics and so avoid coherency problems on the panel. All the timing flags are in the INT_STATUS register and can be used to generate interrupts from the DCU4.

The VS_BLANK and LS_BF_VS flags give indication of the start of the vertical blanking period. The VS_BLANK flag is set at the beginning of the vertical blanking period. The LS_BF_VS flag is set a given number of horizontal lines before the start of the vertical blanking period; the given number of lines is defined by the LS_BF_VS bit field in the THRESHOLD register.

The PROG_END flag indicates that the DCU4 has begun a new panel refresh period. Further changes to the layer control descriptors should not occur until the transfer is complete.

The DMA_TRANS_FINISH flag indicates that the DCU4 has completed fetching all data from memory in the current panel refresh cycle. This normally precedes the vertical blanking period and indicates that it is possible to change the contents of a memory that contains graphics used by the DCU4.

The VSYNC flag indicates that the DCU4 has begun the next panel refresh period.

An additional flag called LYR_TRANS_FINISH is available to indicate when the DCU4 has completed transferring the layer configuration for this refresh cycle. This operates as a functional interrupt rather than a timing interrupt but can also help to ensure data coherency.

55.7.2 Managing the DCU4 FIFOs and DMA activity

The DCU4 fetches graphic data directly from internal and external memory using a dedicated DMA system and manages the output of data to the TFT LCD panel such that the panel always receives the pixel information when expected. Since the panel is sharing access to memory with the system DMA and CPU it cannot depend on the required data always being available at all times. It therefore it uses input and output FIFOs to temporarily store incoming and outgoing data until required and thus reduces the opportunity for the panel to be starved of pixel data.

The DCU4 manages the supply of graphic data to its format conversion and blending stages using input FIFO buffers that are 256 x 64 bits in size. The data that is driven to panel is managed using an output FIFO buffer that is 128 pixels in size. See Figure 55-1 for a diagram of the input FIFO and output FIFO operation in the DCU4

The input FIFOs are not accessible to the user but it is possible to set thresholds that control the DCU4 behavior when the FIFOs are becoming full or empty and observe when the lower and higher thresholds are reached. The DCU4 also provides information on those conditions where data is expected from an input FIFO but is not available. This can help detect and avert situations where the DCU4 is running out of data to send to the panel.

The FIFO thresholds are set in the THRESHOLD_INPUT_BUF_1/2/3 registers. The upper thresholds are set by the INP_BUF_Pm_HI bit fields (where m is the position of the pixel in the blend stack) and these set the point at which the DCU pauses fetching data from memory. The maximum size of any DMA burst is fixed to 16 pixels and so is dependent on the graphic encoding. The lower thresholds are set by the INP_BUF_Pm_LO bit fields.

Each of the six input FIFOs has two flags that indicate whether the FIFO has reached its upper or lower threshold. The Pm_FIFO_HI_FLAG flags (where m is the position of the pixel in the blend stack) indicates that the input FIFO has reached the upper threshold. The Pm_FIFO_LO_FLAG indicates that the input FIFO has less data than its low threshold. Depending on when the low threshold is reached this may indicate a number of scenarios

- The expected graphical data is not available for the DCU4 to load
- The DCU4 is reaching the end of a frame and does not need to load any more data
- The blend stack does not need pixels of this priority

In the situation where the data is not available to the DCU4 then there may or may not be an impact to the data visible on the panel. The DCU4 provides additional information in this case via the Pm_EMPTY flags in the INT_STATUS register and the LINE and PIXEL values in the UNDERRUN register. The Pm_EMPTY flags indicate which position in the blend stack that the latest problem occurred and the LINE and PIXEL entries indicate approximately where on the panel the condition occurred. Taken together this information should allow identification of the source graphic/layer which was too slow to be loaded.

In the situation where the output FIFO is full then it is possible for the DCU4 to accept a delay before it requires to use the incoming data.

The output FIFO is not accessible to the user but it is possible to set thresholds that control the DCU4 behavior when the FIFO is becoming full or empty and observe the lower threshold. This can help detect and avert situations where the DCU4 is running out of data to send to the panel.

The buffer thresholds are set in the THRESHOLD register. The upper threshold is set by the OUT_BUF_HIGH bit field and this indicates that sufficient data exists in the output buffer and processing should stop until the DCU4 uses some of the values in the FIFO. If this value is set too low then the possibility of the DCU4 running out of data to drive the panel is increased. The lower threshold is set by the OUT_BUF_LOW bit field.

When the output FIFO has emptied below its low threshold (OUT_BUF_LOW bit field) it sets the UNDRUN bit. In an under run situation there may or may not be an impact to the data visible on the panel. The impact depends on whether the DCU4 is reaching the end of a frame and how close to running out the threshold is set.

The best guide to indicate whether the DCU4 is able to supply the required pixel information to the panel is the output buffer. If the output is indicating that it is running out of data, the input FIFOs and UNDERRUN register may help identify the areas of memory that are restricting the supply of data. Using these indicators can help to set the DCU4 thresholds and ensure that the data throughput on the MCU is balanced correctly for all master devices.

Finally, note that the number of DCU4 clock cycles to fetch and blend each pixel increases with the depth of the blend stack. However, the time taken to process the pixel data is fixed by the timing requirements of the panel. Therefore, for full performance across all color encodings the ratio between the DCU4 clock and the pixel clock must increase as the blend stack depth increases:

- For two pixel blend, maximum supported pixel clock is DCU4 clock/2.
- For three pixel blend, maximum supported pixel clock is DCU4 clock/3.
- For four pixel blend, maximum supported pixel clock is DCU4 clock/4.
- For five pixel blend, maximum supported pixel clock is DCU4 clock/5.
- For six pixel blend, maximum supported pixel clock is DCU4 clock/6.

55.7.3 Error detection

The DCU4 asserts error flags when errors are detected in its configuration or when the user attempts to modify the configuration at an invalid point in the panel refresh period or when it is unable to access the required source data. The error flags may raise an interrupt if enabled to do so by the related mask bit in the corresponding mask register.

Error flags are stored in the PARR_ERR_STATUS1, PARR_ERR_STATUS2, PARR_ERR_STATUS3, and INT_STATUS registers.

Errors in the DCU4 layer configuration are collected in the PARR_ERR_STATUS1 and PARR_ERR_STATUS2 registers.

The flags Ln (where n is the layer number) indicate an error in the configuration of the layer which can be either an invalid tile mode size or a layer with a horizontal dimension that is smaller than the minimum size defined by the layer encoding (see Layer size and positioning").

Reads of CLUT/Tile RAM during the period when the TFT LCD panel is being updated do not return the CLUT/Tile RAM content.

Errors caused when the DCU is unable to access its required source data are collected in the INT_STATUS register. These errors are indicated by the UNDRUN flag, the Pm_EMPTY flags, and the Pm_FIFO_LO_FLAG flags (where m is the position in the blend stack)

55.7.4 Interrupt generation

The DCU4 generates interrupt through four lines that are controlled by the contents of ten registers:

- INT_STATUS
- INT_MASK
- PDI_STATUS
- PMASK_PDI_STATUS
- PARR_ERR STATUS1
- PARR_ERR STATUS2
- PARR_ERR STATUS3
- MASK_PARR_ERR STATUS1
- MASK_PARR_ERR STATUS2
- MASK_PARR_ERR STATUS3

There are four interrupt status lines defined.These lines are grouped as follows

- Timing based interrupts:
    - VSYNC
    - LS_BF_VS
    - VS_BLANK
    - PROG_END
    - DMA_TRANS_FINISH
- Functional interrupts:
    - UNDRUN
    - LYR_TRANS_FINISH
    - CRC_READY
    - CRC_OVERFLOW

  - P1_FIFO_HI_FLAG
  - P1_FIFO_LOW_FLAG
  - P1_EMPTY
  - P2_FIFO_HI_FLAG
  - P2_FIFO_LOW_FLAG
  - P2_EMPTY
  - P3_FIFO_HI_FLAG
  - P3_FIFO_LOW_FLAG
  - P3_EMPTY
  - P4_FIFO_HI_FLAG
  - P4_FIFO_LOW_FLAG
  - P4_EMPTY
  - P5_FIFO_HI_FLAG
  - P5_FIFO_LOW_FLAG
  - P5_EMPTY
  - P6_FIFO_HI_FLAG
  - P6_FIFO_LOW_FLAG
  - P6_EMPTY
  - IPM_ERROR
- Parameter error interrupts
  - Layer Error
  - Signature Calculator Error
  - Display Error
  - HWC_error
- PDI-related interrupts (pdi_int)
  - This includes PDI related interrupts. See PDI-Related Interrupts for a description.

When any interrupt occurs, the host can identify which type of interrupt has occurred by reading the interrupt status register and PARR_ERR status registers.

55.8 Register protection

There is a customized register protection scheme on the DCU4. The scheme provides a mechanism to protect certain registers in the DCU4 from being written.

55.8.1 Operation of scheme

The register protection scheme provides a two-step protection scheme for the protected register.

Firstly, each register has an associated soft lock bit (SLB) that prevents further writes to the register when it is set. Each SLB has a corresponding write enable (WEN) bit that must be set in the same write operation as the SLB. The SLB can be set or cleared by writing a '1' or '0' to it while its WEN bit is set. The SLB bits are in the Soft Lock Registers L0 and L1, DISP_SIZE, HSYNC/VSYNC_PARA, POL, L0_TRANSP and L1_TRANSP registers.

Secondly, there is a hard lock bit (HLB) in the Global Protection Register which prevents all changes to soft lock bits. The HLB can only be cleared by a system reset.

If a write is made to a register whose SLB is set then a transfer error occurs that generates a data abort on the CPU. Similarly if the HLB is set then any write to the SLB registers causes a transfer error.

55.8.2 List of protected registers

The register protection scheme applies to the following registers:

- All Layer 0 control descriptors CTRLDESCL0_1 to CTRLDESCL0_9
- All Layer 1 control descriptors CTRLDESCL1_1 to CTRLDESCL1_9
- DISP_SIZE
- HSYNC_PARA
- VSYNC_PARA
- SYNPOL

55.9 Safety Mode

Safety layers are used in a multi-layer DCU4 environment for the purpose of guaranteeing that the content is driven to the display regardless of the setting of remaining layers and the pixel manipulation algorithms of the DCU4. Features such as this are a requirement from qualification institutes to be able to reach a safety level of SIL2 or ASILB. The DCU4 has two safety layers (Layer 0 and Layer 1) which also have the highest priority. When Safety Mode is active the safety layers can use chroma keying for complex area description, however alpha blending for the layer is always ignored. Additionally, if a layer has safety mode enabled then a layer format of 32 bpp or luminance is not allowed. Using these formats causes the layer to be disabled.

Safety Mode is implemented using a signature calculator module implemented inside the DCU4 that calculates two signatures (pixel value and pixel position) for a predefined area of the frame. The user makes layer 0 and/or layer 1 active as a safety layer, defines the window/area of the pixels for which the signature is to be calculated, and enables safety mode. When enabled, the signature calculator starts to calculate the signature after the first pixel in the selected area is available and after the start of the next frame (VSYNC). It is also possible to calculate the signature value for all pixels if DCU_MODE[TAG_EN] = 0.

As the pixels in the selected area become available they are "tagged" by the DCU4, except for those removed by chroma-keying. These tags identify the pixels to be included in the signature calculation. The signature calculation itself is an industry-standard CRC.

The DCU4 asserts the CRC_READY flag at the end of any frame which has Safety Mode enabled. This can be used to indicate the completed signature calculations for each full frame of pixels after the mode is enabled. The completed signature can then be compared against a pre-calculated value with any difference indicating that the pixels displayed did not match what was expected. The signature calculator then continues to calculate the CRC for the next frame. If the CRC_READY flag is not processed within one frame time period, then the CRC_OVERFLOW interrupt is issued and the latest calculation overwrites the previous value. Since the CRC_READY flag is set at the end of any frame with Safety Mode enabled, it is possible that a full frame has not yet been completed and therefore no signature calculation exists for the frame that set the flag.

If the user has set the NEG bit for the DCU4 which indicates that the pixels fed to the display are inverted, then the value CRC is calculated on non-inverted values. The position CRC, however, remains as is.

Normal arbitration takes place only when a pixel has content on layer 0 and layer 1 but where Safety Mode is enabled in layer 1.

The polynomial used for CRC calculation is (x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1).

For the value CRC, the 24-bit value of each output pixel (after decoding) is sent to the polynomial. For the position CRC, the value sent is (pixel_delta_y * display.delta_x) + (pixel_delta_x + 1).

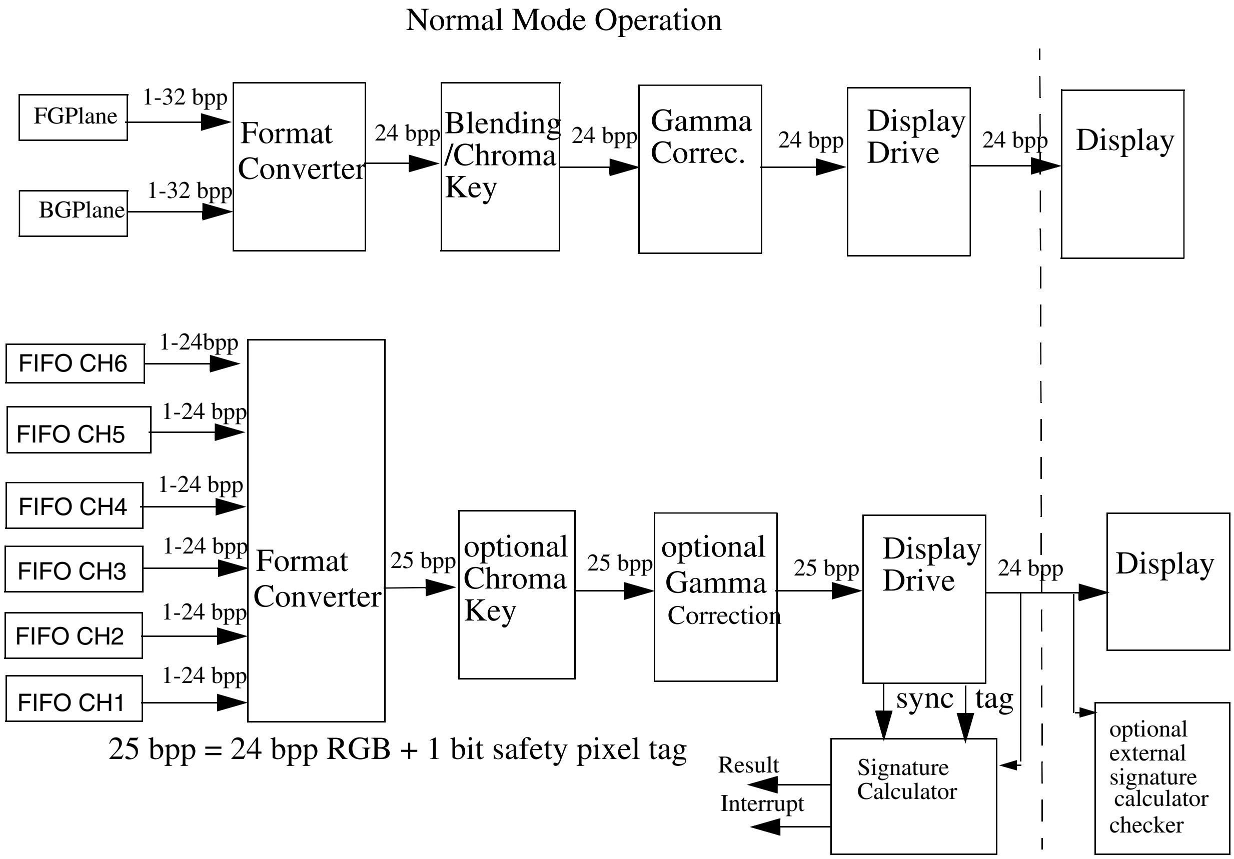

Figure 55-1951. Safety Mode Block Diagram

55.9.1 CRC Area Description

55.9.1.1 Relationship between various input signals

To configure the CRC calculation:

1. CRC_VAL and CRC_POS are calculated when Safety Mode is enabled using DCU_MODE[SIG_EN].

2. The CRC can be calculated for part of the panel as shown in the following figure. The green portion on the panel is identified using the SIGN_CALC_1 and SIGN_CALC_2 registers which defined the size of the area and the location of the area respectively. If SIGN_CALC_1 and SIGN_CALC_2 are configured appropriately this calculation will cover the whole panel.

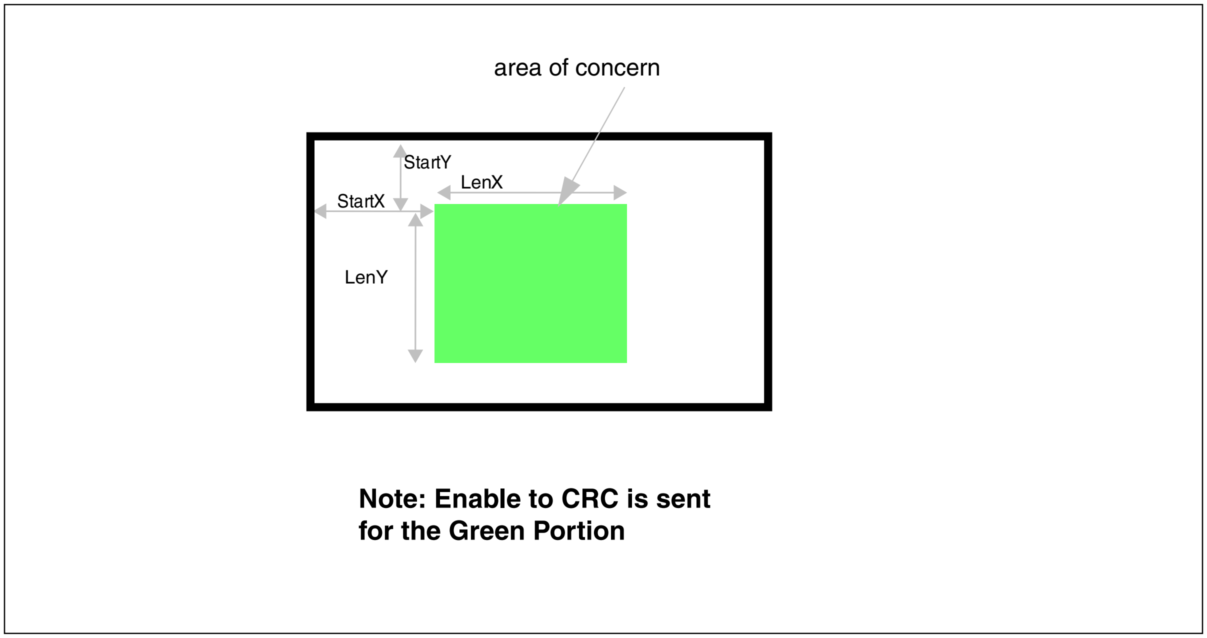

Figure 55-1952. Safety Mode enabled for part of the screen

3. The CRC can be calculated exclusively for layers 0 and 1 by setting DCU_MODE[TAG_EN] and enabling the SAFETY_EN bit in control descriptor 4 of each of the layers. In this configuration the CRC is calculated using values from the layers only where they intersect the area of interest defined in SIGN_CALC_1 and SIG_CALC_2. An example is shown (in dark pink) in the following figure.

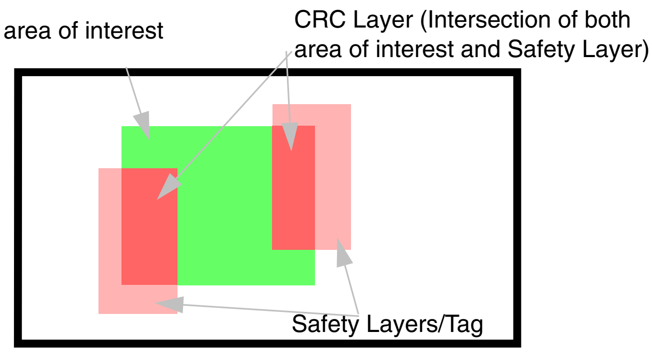

Figure 55-1953. Safety Mode with tag bit high

4. Layer 0 and 1 (i.e., safety layer) in safety mode does not supports blending or luminance offset.

55.9.1.2 Features

- SC support area modes mentioned in Table 55-1950
- Supports calculation of CRC on the pixel value only
- CRC is calculated with the initial value as 32'h000000000
- CRC does not support:
  - Any modification of input bytes
  - Any modification of the output CRC value before reporting.
- When PDI is enabled with the Layer 0 and 1 (safety enabled) in a single sector, then PDI would act as BG layer and Layer 0 as a FG Layer.CRC would be calculated over a single L0 Layer.

Table 55-1950. Supported Area

Area	Tag Value	Note
Full	1'b0	StartX = 0 StartY = 0 LenX = Screen Size LenY = Screen Height
Part	1'b0	All the parameter have value other the one mentioned above as shown in Figure 55-1952.
Safety Layer (Layer 0 and 1 only)	1'b1	Part of the safety Layer would depend on • Part lying within the area of concern defined by the StartX startY LenX LenY • Part deleted by the chroma keying functionality

55.9.1.3 Summary of Operation

The area included in the CRC calculation is summarized in the following table. The initial value on all CRC calculations is 0x00000000.

Table 55-1951. CRC calculation area

Area	DCU_MODE[TAG_EN]	Note
Full	0	SIGN_CALC_2[SIG_HOR_POS] = 0 SIGN_CALC_2[SIG_VER_POS] = 0 SIGN_CALC_1[SIG_HOR_POS] = Panel Width SIGN_CALC_1[SIG_VER_POS] = Panel Height
Part	0	The SIGN_CALC parameters have values other than those mentioned above. See figure 11-86.
Safety Layer (Layer 0 and 1 only)	1	The included portion of the safety layers depends on: – The portion lying in the area defined by SIGN_CALC1 and SIGN_CALC12 – The pixels removed by chroma keying functionality

55.10 Parallel Data Interface (Camera Interface)

55.10.1 PDI Interface Description

55.10.1.1 Introduction

This block extracts the timing and pixel information from an external video source and passes it to the DCU4 block to synchronize with the timing and display the pixel information on the TFT LCD screen. The BGND layer in the DCU3 is replaced by the incoming video stream.

The PDI requires that the incoming video stream match the resolution and timing at which the DCU4 is driving the TFT LCD panel and the incoming stream must not be interlaced.

The PDI can also be configured in slave mode in which case it ignores the pixel information from the external video source and only passes the timing information to the DCU4 to synchronize with. In this instance the DCU3 will continue to operate as normal (the BGND layer will not be altered) but will use the timing from the PDI.

The PDI shares configuration registers with the DCU4.

55.10.1.2 PDI Interaction With Other Modules

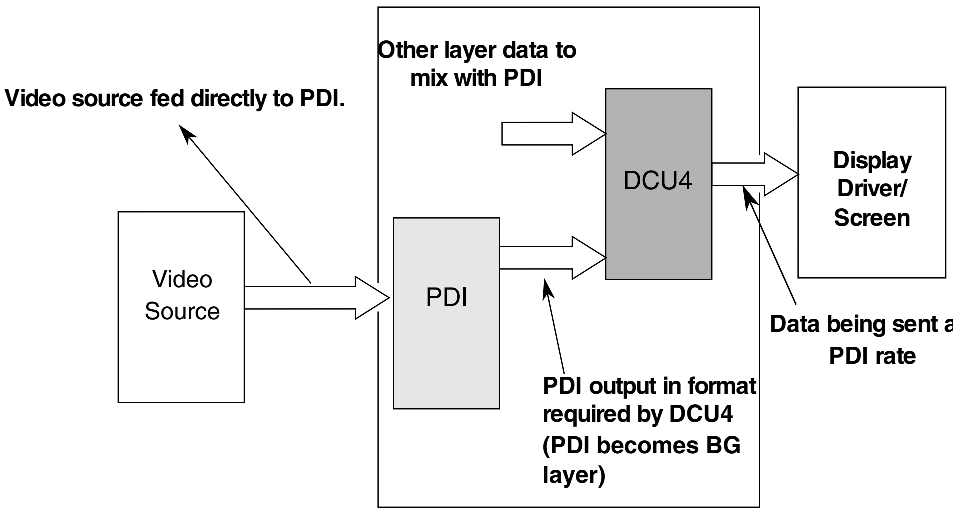

Figure 55-1954. PDI Interacting Directly with the External Sensor

In Figure 55-1954, PDI directly accepts the data from the external video source. External device must support the interface mentioned in the document.

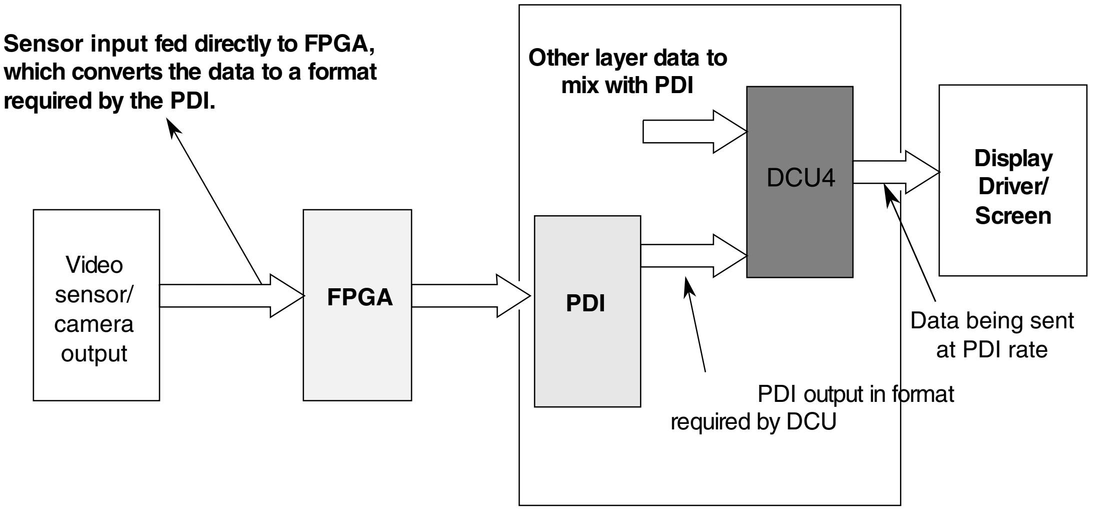

Figure 55-1955. PDI Interacting with FPGA in Between

As shown in the figure above, the video stream is sent to a decoder or an FPGA which alters the incoming stream to a format which is compatible with the PDI. A decoder/ FPGA is required if a video source with an analog output format (e.g. NTSC/PAL) is used. The decoder should perform analog-to-digital conversion on the stream and ensure the timing match that of the DCULite. The incoming stream may also need to be de-interlaced.

The PDI is compatible with various input formats:

- Normal Mode: The PDI clock frequency must be equal to the pixel clock frequency required by the TFT display driver.
- Narrow Mode: The PDI clock frequency is double the desired pixel clock frequency.
- External Synchronization: The timing signals (HSYNC, VSYNC, and DE) each have a dedicated input pin. (DE is optional).
- Internal Synchronization: The timing signals (HSYNC, VSYNC and DE) are embedded in the data stream, as such only the DATA and PCLK inputs are required. (See ITU-R BT.656 sync information extraction.)

Before the DCULite locks onto the PDI timing signals it will run on the internal DCULite clock. After lock has been achieved, the DCULite will switch to the clock from the PDI stream and the this is then used to send data and timing signal to TFT/LCD display driver.

In all cases, the resolution of the incoming stream and the HSYNC and VSYNC frequency must be the same as that for TFT screen. All the horizontal parameters (Front Porch width, Back Porch width, Pulse width) and vertical parameters (Front Porch width, Back Porch width, Pulse width) must be same as that of TFT screen.

When PDI is the background layer, no other layer can be a background layer for that particular frame. Only one background layer is possible i.e. PDI Layer when PDI is enabled.

55.10.1.3 Features

The PDI supports the following:

- RGB565, RGB666, 8 bit monochrome format,YCbCr422 mode
- Max input frequency of 32 MHz in 8/16/18 normal mode input
- Max input frequency of 64 MHz in 8 bit muxed (narrow) mode.
- External Synchronization using PDI_Hsync, PDI_Vsync, and PDI_PCLK
- External Synchronization using PDI_Hsync, PDI_Vsync, and PDI_PCLK, and PDI_DE
- Internal synchronization using PDI[17:0] and PDI_PCLK is supported for RGB565 and YCbCr422 muxed modes only.

Table 55-1952. Supported RGB formats and sync formats

RGB Format	Data Input Bus
8-bit monochrome	8 bit
RGB565	16 bit
RGB666	18 bit
RGB565 muxed (uses narrow mode)	8 bit
YCbCr	8 bit
Sync Format	**Pin Used**
Internal Sync (Valid only for RGB565 and YCbCr in narrow mode)	PCLK
External Sync	PDI_HSYNC, PDI_VSYNC, PDI_PCLK
External sync (with data En)	PDI_HSYNC, PDI_VSYNC, PDI_PCLK, PDI_DE

55.10.1.4 ITU-R BT.656 sync information extraction

According to ITU-R BT.656 recommendation, the incoming digital video will have a pdi_clk signal and 8 data bits. The data bits can contain both the video data and the timing reference signals (VSYNC and HSYNC).

The timing signals are encoded at the start and end of each line by timing reference codes known as Start of Active Video (SAV) and End of Active Video (EAV). The SAV and EAV codes are identified by their preamble of three bytes (0xFF,0x00,0x00). Due to this, neither 0x00 or 0xFF can be used during the Active Video Data. The preamble is followed by the XY status word which contains a Field Bit (F), a Vertical blanking bit (V) and Horizontal blanking bit (H) and four protection bits for single bit error correction and detection.

The H bit is set to 1 to denote an EAV — that is the end of a line, and the beginning of the horizontal blanking period. The V bit is set to 1 to denote the beginning of the vertical blanking period. The F bit is used for interlaced video to denote if the forthcoming line is odd or even.

The remaining 4 bits contains make up the protection bits for single bit error correction and detection. It should be noted that F and V fields are only allowed to change as part of EAV sequences i.e during transitions from H=0 to H=1.

An entire line of video comprises Active Video + Horizontal Blanking (from the start of the EAV code until the end of the SAV code) and Vertical Blanking (the space where V = 1).

NOTE

This device supports only 8-bit, non-interlaced, video. The Field (F) value is ignored.

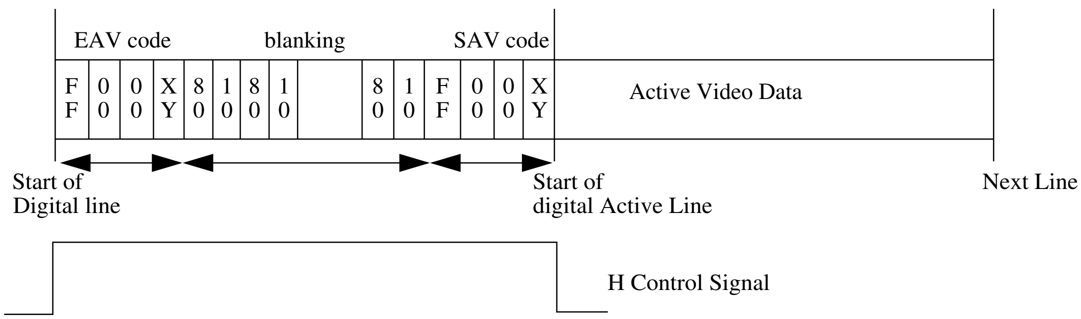

Figure 55-1956. ITU-R BT.656 8 bit parallel data format for 525 video system

Table 55-1953. Control Byte Sequence for 8-bit/10-bit video

Data Bit	FirstWord (FF)	SecondWord (00)	ThirdWord (00)	Fourth Word (XY)
D7(MSB)	1	0	0	1
D6	1	0	0	F
D5	1	0	0	V
D4	1	0	0	H
D3	1	0	0	P3
D2	1	0	0	P2

Table continues on the next page...

Table 55-1953. Control Byte Sequence for 8-bit/10-bit video (continued)

Data Bit	FirstWord (FF)	SecondWord (00)	ThirdWord (00)	Fourth Word (XY)
D1	1	0	0	P1
D0 (LSB)	1	0	0	P0

The bit definitions for the status word XY are:

F = 0 for field 0

F = 1 for field 1

V = 1 during vertical blanking period

V = 0 when not in vertical blanking

H = 0 at SAV

H = 1 at EAV

P3 = V XOR H

P2 = F XOR H

P1 = F XOR V

P0 = F XOR V XOR H

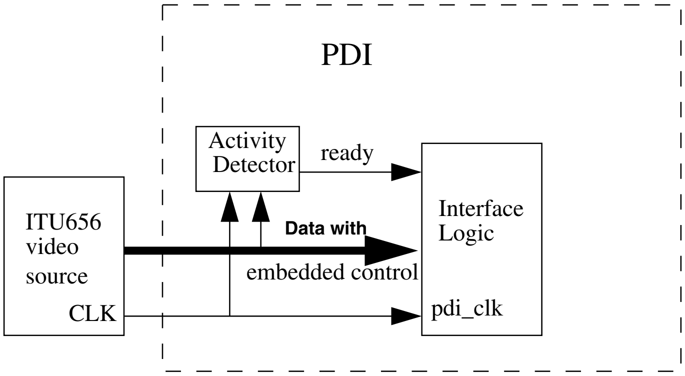

Figure 55-1957. PDI Input data mode

Figure 55-1957 represents the scenario in which data from an ITU-R BT.656 compliant video source is fed into the PDI interface. The incoming data includes codes that trigger the start and end of the active video and blanking fields. An activity detector checks for the transitions on the PDI bus. It samples the values on the PDI bus and once it has detected valid activity, sets a flag in the status register and can optionally trigger an interrupt. The PDI interface has a state machine which extracts the control information

from the video data. The machine checks the video data for the Preamble Field (0xFF, 0x00,0x00) and then depending on the status bits XY decides if it has received a valid control signal.

55.10.1.5 Normal and Narrow Mode

In normal mode, PDI support maximum input frequency of 32 MHz. In narrow mode, PDI supports maximum input frequency of 64 MHz.

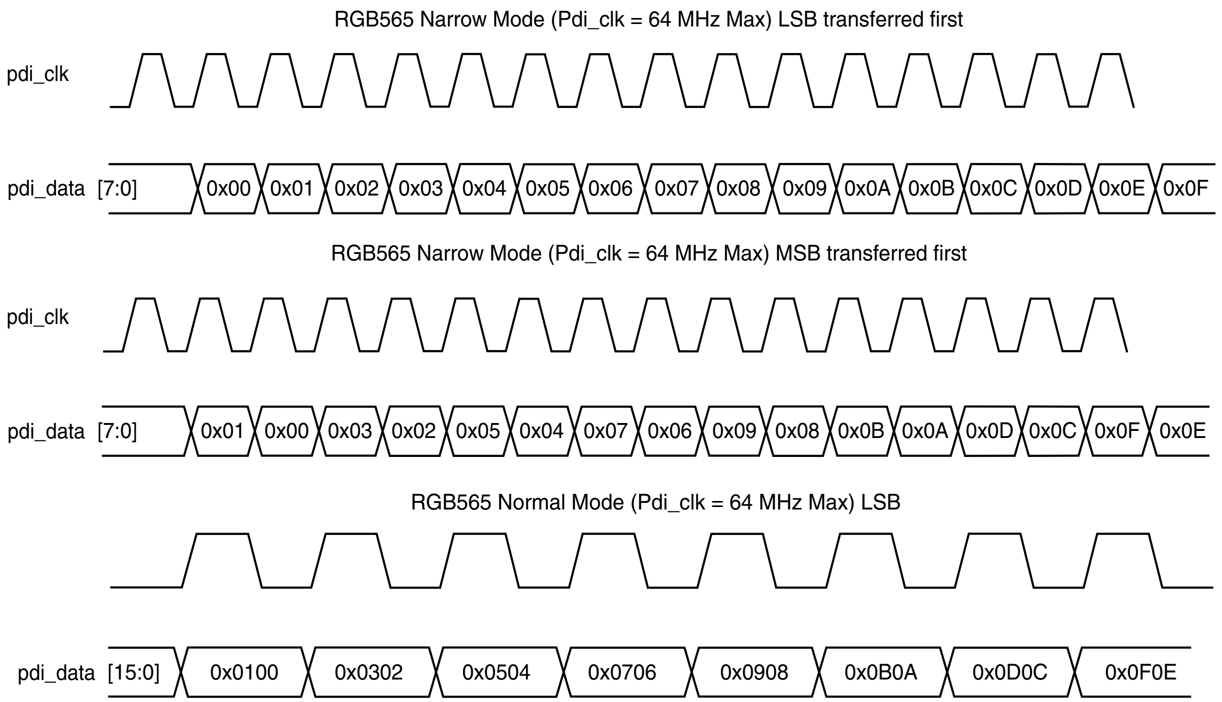

Figure 55-1958. Data Transfer in Normal and Narrow Mode

The byte transferred first (MSB or LSB) depends on the configuration register as shown in Figure 55-1958.This would not effect the sync preamble sequence in case internal sync mode.

On this device, the incoming RGB data is mapped onto the PDI pins as described in the following table.

Table 55-1954. Mapping of RGB data onto PDI pins

Mode	Mapping
Normal (full 18-bit PDI interface)	PDI[17:12] = DCU4_R[5:0] PDI[11:6] = DCU4_G[5:0] PDI[5:0] = DCU4_B[5:0]
Normal (RGB565 16-bit PDI interface)	PDI[15:11] = DCU4_R[4:0] PDI[[10:5] = DCU4_G[5:0] PDI[4:0] = DCU4_B[4:0]

Table continues on the next page...

Table 55-1954. Mapping of RGB data onto PDI pins (continued)

Mode	Mapping
Narrow (8-bit PDI interface)	RGB565: In first clock cycle, PDI[7:0] = { DCU4_R[4:0], DCU3_G[5:3] }. In second clock cycle, PDI[7:0] = { DCU3_G[2:0], DCU3_B[4:0] }. YCbCr: In first clock cycle, PDI[7:0] = { DCU3_Cb[7:0] }. In second clock cycle, PDI[7:0] = { DCU3_Y0[7:0] }. In third clock cycle, PDI[7:0] = { DCU3_Cr[7:0] }. In forth clock cycle, PDI[7:0] = { DCU3_Y1[7:0] }.

55.10.1.6 Modes of Operation Based on Sync Extraction

55.10.1.6.1 PDI input data (external sync mode)

In external sync mode the timing signals (HSYNC, VSYNC and, optionally, Date Enable) are provided to the PDI input timing pins by the external video source.

External sync mode can be used in both normal mode and 8-bit narrow mode, but cannot be used in conjunction with the YCbCr data format. In the instance that external sync and narrow mode is selected, the external signals are used, and any timing information (EAV/SAV) embedded in the data stream is ignored.As in Figure 11-95, PDI data enable (PDI_DE) should be low during VSYNC and HSYNC pulse, VSYNC front porch (FP_V) and back porch (BP_V), HSYNC front porch (FP_H) and back porch (BP_H). This is valid for Data Enable Mode when the PDI_DE_EN bit is set in the DCU_MODE register (i.e. mode with HSYNC, VSYNC, PDI_DE and PDI_PCLK as pin signals).

As in Figure 55-1960, PDI data enable (PDI_DE) should be low during VSYNC and HSYNC pulse, VSYNC front porch (FP_V) and back porch (BP_V), HSYNC front porch (FP_H) and back porch (BP_H). This is valid for Data Enable Mode when the PDI_DE_EN bit is set in the DCU_MODE register (i.e. mode with HSYNC, VSYNC, PDI_DE and PDI_PCLK as pin signals).

Pulse width, Front and back porch values should be picked from those programmed in DCU3 registers. In order to achieve lock, it must have same value as that of TFT screen. Front porch and back porch value can be zero. Pulse width and TFT screen size parameters cannot be zero. In case they are programmed as zero, it might lead to malfunctioning of the validation state machine.

As in Figure 55-1959 Figure 11-94 HSYNC must occur during the VSYNC and vertical blanking period. The time between 2 HSYNC should be the same during VSYNC and vertical blanking as during the active line period. As in Figure 11-94 the positive edge of HSYNC and VSYNC should be aligned. As in Figure 11-94 the positive edge of the HSYNC and start of the vertical front/back porch should be aligned.

The polarity of HSYNC and VSYNC is selectable.

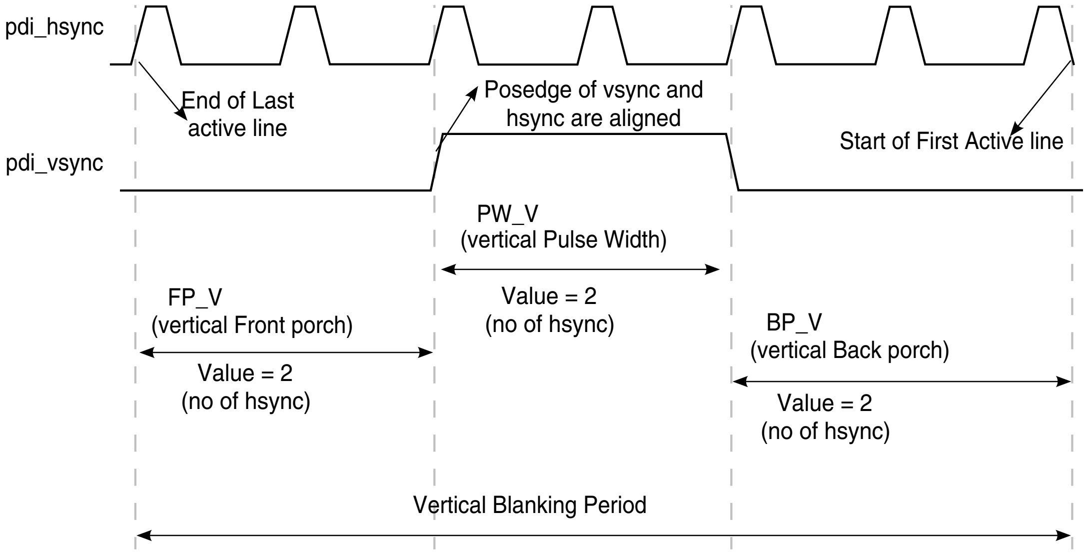

Figure 55-1959. Relation between Hsync and Vsync in external synchronization

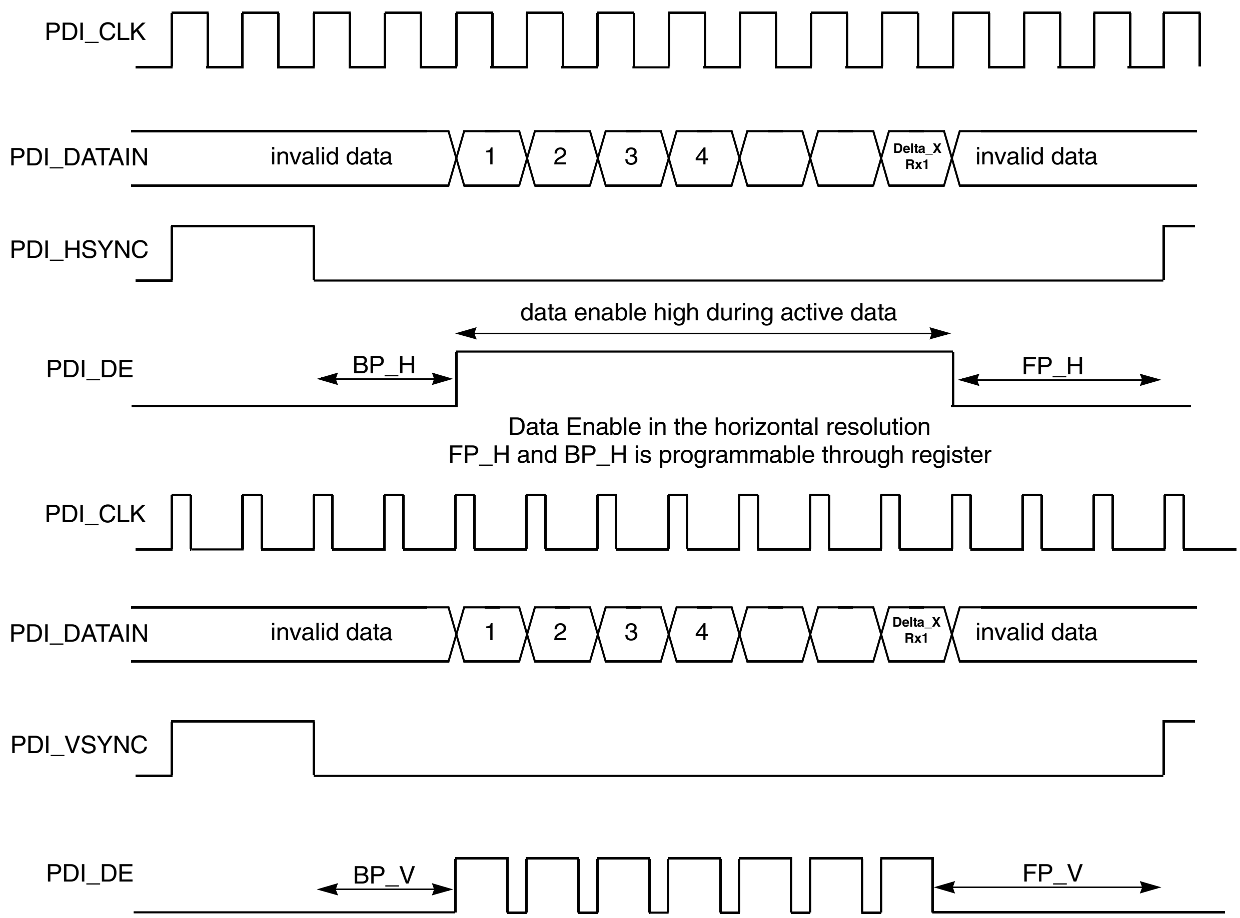

Figure 55-1960. Occurrence of Hsync and Vsync and DataEn for the entire frame

55.10.1.6.2 PDI Input data (Internal Sync Extraction mode)

In internal sync mode the timing parameters (horizontal and vertical blanking) are encoded into the data stream.

Internal sync mode can only be used in 8-bit narrow mode.

In Figure 55-1961, XY is used to decode the vertical and horizontal blanking period.

Table 55-1955. XYh Value

Bit	Value	Description
7	1'b1	Always 1'b1. This is checked while decoding sync preamble
6	F	Not considered in the state machine logic

Table continues on the next page...

Table 55-1955. XYh Value (continued)

Bit	Value	Description
5	V	1'b1 during vertical blanking 1'b0 elsewhere
4	H	1'b0 for start of active video 1'b1 for end of active video
3 2 1 0	P3 P2 P1 P0	Protection bits (used to detect ECC errors). It would not be used for bit correction.

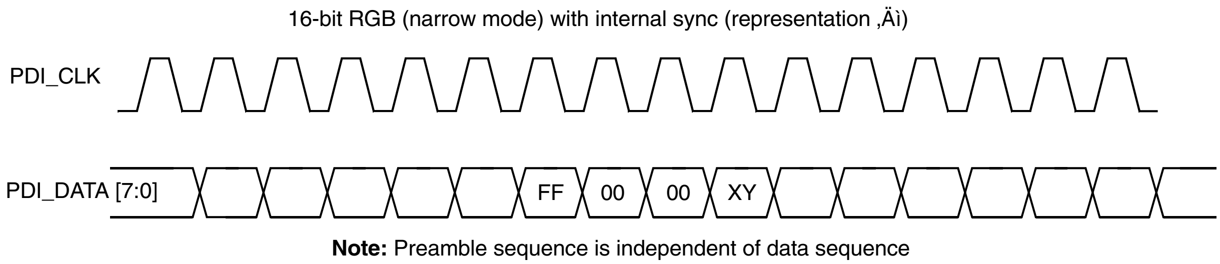

Figure 55-1961. Location of sync preamble in narrow mode

Sync Preamble would come continuously for 4 clock cycles as shown in Figure 55-1961. It does not depend upon which byte is coming first in data (MSB or LSB). Sync extraction is done using PDI_DATAIN[7:0] to identifies the horizontal and vertical blanking period using H and V field of the 'XYh' data as mentioned in Table 55-1955.

ITU 656 Sync preamble pattern (FFh 00h 00h) has to be masked out in the RGB and YCbCr data. The data stream must not include FFh 00h 00h as the valid pixel data to avoid malfunction by the validation state machine.

Horizontal blanking period must continue during the Vertical blanking period. The gap between 2 horizontal blanking periods should be the same during vertical blanking period as during line active. All Vertical and horizontal parameter values are validated against the DCU3 registers programmed by the user. Polarity of HSYNC and VSYNC are selectable. Horizontal blanking and vertical blanking must be aligned as shown in Figure

55-1962. During blanking period the input stream must be a 80h 10h 80h 10h sequence. This sequence must be present during both horizontal (line) blanking and vertical (frame) blanking.

As the PDI does not support interlaced video, the Framing Bit (F field in XYh) will be ignored during timing extraction. Narrow mode is compatible with RGB565 and YCbCr422 muxed modes. Each header contains an ECC value, which the PDI will check. The PDI is capable of detecting an error but not correcting it.

As with External sync mode, the value of front and back porch can be zero but the pulse width and TFT screen parameter cannot be zero.

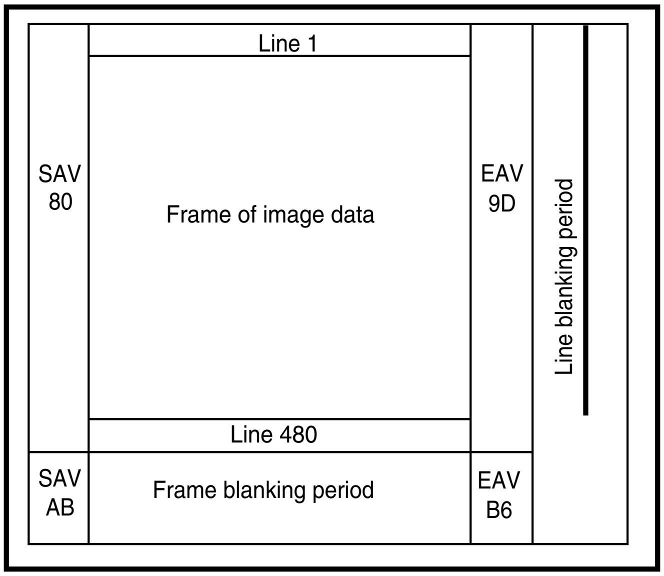

Figure 55-1962. Relationship between Hblank and Vblank in internal sync

55.10.1.6.3 PDI YCbCr mode and DCU4 YCbCr color format

The DCU4 can process incoming data from the PDI and from memory in YCbCr422 format. Both sources use the same RGB conversion and interpolation equations, however, the coefficients for the equations and enable for the interpolation are independently controlled.

In YCbCr mode, the PDI extracts the ITU656 sync (FF-00-00) and sends the video to the processing functions. The first processing function converts the 422 stream to a 444 stream, by providing interpolation on the chroma components of the stream depending on PDI_INTERPOL_EN bit. The second processing function converts the stream to RGB888/RGB565.

The DCU4 can also select YCbCr format in the BPP field of layer descriptor 4, which allows the same process to be applied to values stored in memory rather than brought in from the PDI. Interpolation is controlled for the layers using the LYR_INTPOL_EN register.

The RGB pixel value is computed using following equations:

$$\text{Red} = \frac{(Y-16).\text{yred}}{512} + \frac{(\text{Cr}-128)\text{Crred}}{512} + \frac{(\text{Cb}-128)\text{Cbred}}{512}$$

$$\text{Green} = \frac{(Y-16).\text{Ygreen}}{512} + \frac{(\text{Cr}-128)\text{Crgreen}}{512} + \frac{(\text{Cb}-128)\text{Cbgreen}}{512}$$

$$\text{Blue} = \frac{(Y-16).\text{yblue}}{512} + \frac{(\text{Cr}-128)\text{Crblue}}{512} + \frac{(\text{Cb}-128)\text{Cbblue}}{512}$$

NOTE

The first multiplication, ((y –16) * ycoeff), is unsigned, the two others are signed.

The register values after reset are as follows:

Yred = 10'h254 (596/512 = 1.16)

Crred = 11'h331 (817/512 = 1.6)

Cbred = 12'h000

Ygreen = 10'h254(596/512 = 1.16)

Crgreen = 11'h660(-416/512 = –0.812)

Cbgreen = 12'hf38(-200/512 = –0.39)

Yblue = 10'h254(596/512 = 1.16)

Crblue = 11'h000

Cbblue = 12'h409(1033/512 = 2.017)

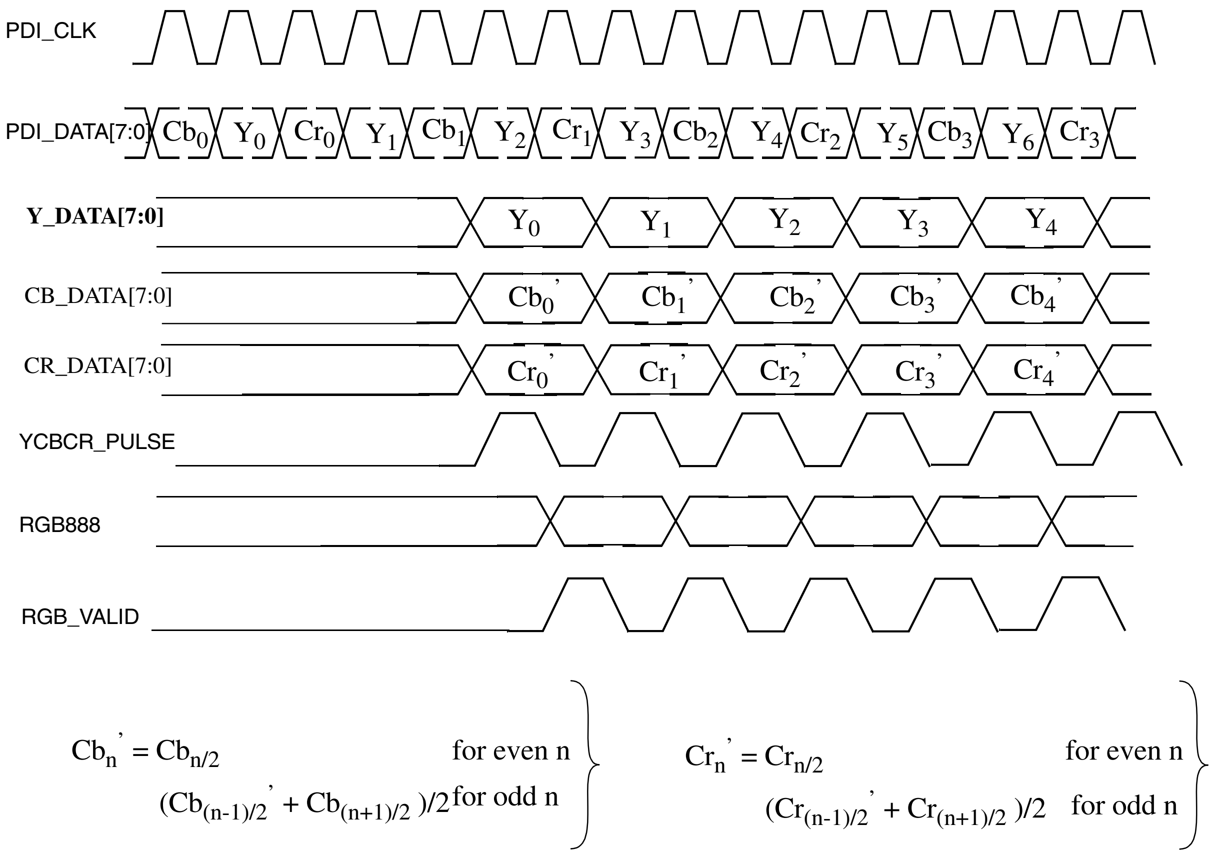

Figure 55-1963. YCbCr timing diagram

55.10.1.7 Mode of operation depending on PDI[17:0]

PDI supports following modes (other than the Slave Mode):

- 8-bit monochrome (8-bit input data, each pixel info is coming in 1 clock)
- 16-bit – RGB565 (16-bit input data, each pixel info is coming in 1 clock)
- 18-bit – RGB666 (18-bit input data, each pixel info is coming in 1 clock)
- 16-bit – RGB565 (8-bit input data, each pixel info is coming in 2 clocks)
- 16-bit – YCbCr422 (8-bit input data, info for 2 co-sited pixels coming in 4 clocks)

Data info extraction is given in Table 55-1956.

Table 55-1956. Data extraction in all possible modes

PDI Mode	Narrow Mode	Pins	Data	Notes
8-bit monochrome mode	1'b0	8 bit	PDI[7:0]	—
RGB565	1'b0	16 bit	PDI[15:0]	—
RGB666	1'b0	18 bit	PDI[17:0]	—
RGB565 muxed	1'b1	8 bit	PDI[7:0]	Data from two clocks are combined.
YCbCr422	1’b1	8 bit	PDI[7:0]	Data from four clocks are combined for 2 pixels.

The 8-bit monochrome image is equivalent to 8-bit grayscale images. For converting 8-bit monochrome data to RGB data, each of the R/G/B components will have a value equal to the 8-bit monochrome value.

RGB extraction starts when PDI is enabled (from the next falling edge of validated vertical blanking period)

55.10.1.8 PDI-Related Interrupts

PDI can be configured to trigger an interrupt when synchronization is achieved i.e. it receives the prespecified numbers of frames without error. PDI can also give an interrupt when synchronization is lost i.e. it receives any error in frame there after. This interrupt is raised when HSYNC/VSYNC is lost.

The PDI can also trigger an interrupt if there is either a one bit or a multiple bit error in the ECC value during the extraction of the preamble in internal synchronization mode.

Blanking sequence error interrupt can be triggered in case 80h 10h is not found in vertical and line blanking period during internal synchronization.

Activity detection interrupt for CLK detection.

HSYNC, VSYNC and DE detection interrupts can be set to generate upon transitions on the PDI_HSYNC, PDI_VSYNC and PDI_DE pins.

Activity lost interrupt for PDI_CLK — for the PDI_CLK lost interrupt, is triggered when the PDI_CLK is less than DCU3 module clock frequency divided by 32. (i.e. if DCU3 module clock freq. max = 64 MHz, then the PDI_CLK_LOST flag will be set if pdi clk freq. min < 2 MHz).

All interrupts are RW1C (write one to clear). All interrupts are maskable.

PDI must reset to show the latest status of the clock activity detect interrupt.

55.10.2 Switch between DCU mode and PDI mode (top-level description)

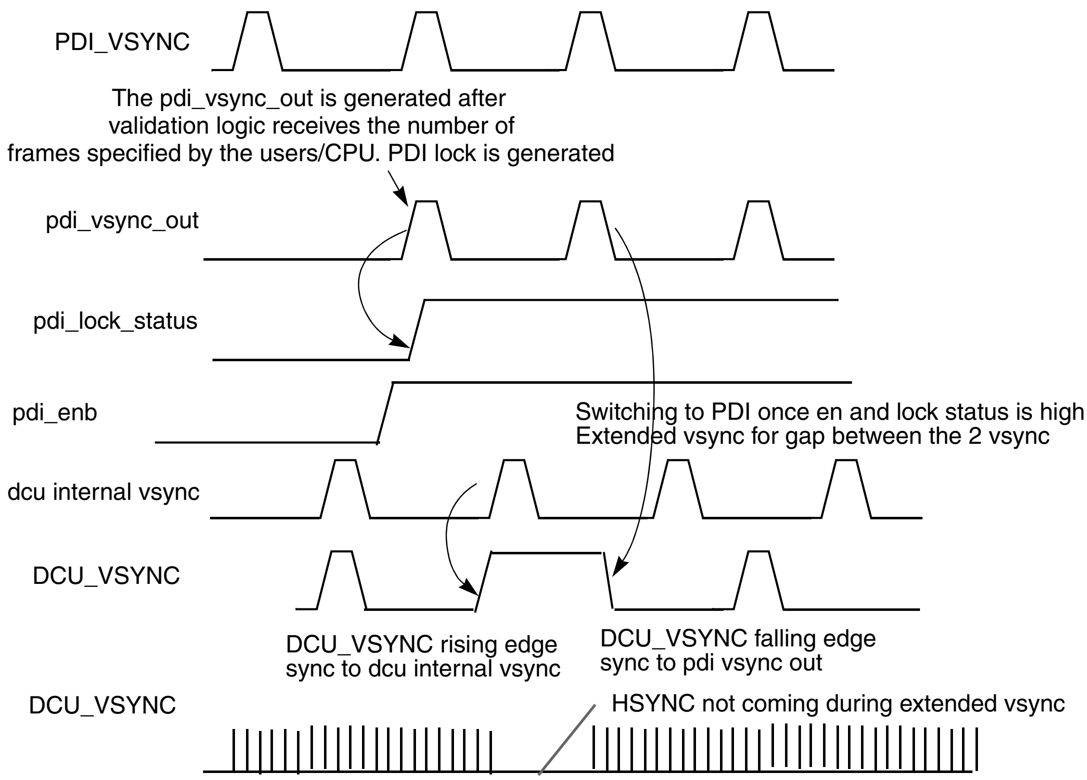

Figure 55-1964. Switch to PDI on receiving the interrupt

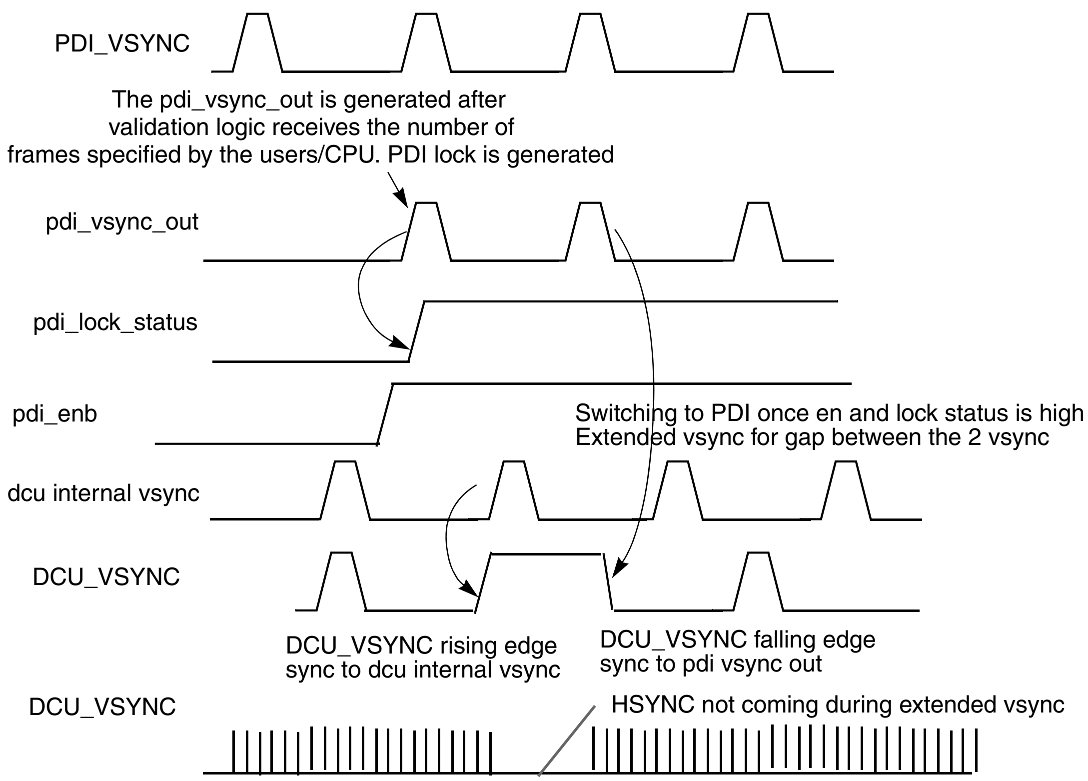

Figure 55-1965. Switch to Normal Mode from PDI mode

55.10.2.1 Changes in the configuration

Any changes in the RGB format or the synchronization mode configuration requires the PDI system to be in disable mode i.e. PDI_EN should be 0 during this time. The resolution of the screen/layer (PDI or TFT) cannot change on the fly.

55.10.2.1.1 PDI slave mode

The VSYNC generated by the DCU4 block is synchronized to the PDI input VSYNC; the PDI VSYNC resets the internal timing generation unit. HSYNC and VSYNC are generated internally corresponding to the external TFT screen display parameters programmed in the DCU4 registers.

55.10.2.1.2 PDI sync detection/validation

PDI declares a lock when it has correctly received the continuous number of frames programmed by the application.

PDI declares the sync lost:

- When it receives data enable during the vertical and horizontal blanking period (in case of data enable mode).
- When the incoming HSYNC and VSYNC timing does not match the programmed parameter values in the DCU3. This also means that if any of control signal info lost, then it also declares sync lost.

After PDI_PCLK is lost, the PDI requires 64 DCU3 module clock cycles to detect PDI_PCLK again.

PDI does not declare lost sync in case of blanking and ECC errors.

Writes to the input FIFO are stopped as soon as PDI sync is lost aborting transfer of the current frame data. Sync detection works continuously, independent of PDI enable. PDI fires an interrupt on:

- Sync lock is achieved
- Sync is lost
- Activity is detected on hsync
- Activity is detected on vsync
- PCLK activity detection (it is not generated from the state machine)
- DE Activity detection (it is not generated from the state machine)
- PCLK activity lost (it is not generated from the state machine)

On receiving a wrong sync pulse, the DCU4 stops the HSYNC and VSYNC activity detection and gives an interrupt when it finds sync pulse again. The state machine works for zero values of front and back porches but not for pulse width and screen parameters.

55.10.2.1.3 Other assumptions

The reset to the PDI clock is synchronized to the peripheral clock. Reset synchronization is done with respect to the PDI clock internally.

The PDI clock should be available at least 10 clock after the last valid data. This corresponds to the delay of the PDI block.

55.11 DCU4 Initialization

The following steps describe a typical approach to initializing the DCU4 for use in an application.

1. After reset, configure the DCU4 peripheral to be active and configure the DCU4 clock source.
2. If using a panel with an integrated TCON module, disable the TCON signals by setting the TCON_BYPASS bit in the TCON CTRL1 register. Due to the configuration of the TCON module, the DCU4 pixel clock signal will be output as soon as it is selected by the related IOMUX register. This is independent of the DCU4 operating mode.
3. Configure the output ports in the IOMUX registers as required.
4. Configure the timing registers to match the TFT LCD panel in use (see TFT LCD panel configuration).
5. Set the background color as required.
6. Load the initial tile or palette colors into the CLUT/Tile memory.
7. Initiate a manual refresh of the frame by setting the READREG bit in the UPDATE_MODE register.
8. If Automatic transfer is required, wait until the READREG bit is cleared before setting the MODE bit in the UPDATE_MODE register

55.12 Glossary

Table 55-1957. Glossary

ARGB (also BGRA)	A data format where the pixel values are stored using four components: Alpha, Red, Green and Blue. DCU4 supports different variations of this format where different numbers of bits can be used to represent each of the components
Component	Part of a pixel that contains a single color (red, green or blue)
CLUT	Color Look-up table. The table that contains the palette used by an indexed-color graphic
Direct color	The full 24-bit value actually written to a pixel to create a color
Frame	The collection of all pixels on a panel
Gamut	The set of colors that a panel can display. In most cases a panel cannot display the full gamut of colors visible to the human eye.
Indexed color	An index into a table containing direct-colors. Usually smaller in size than the direct color; the DCU4 provides 1, 2, 4, and 8 bits per pixel options

Table continues on the next page...

Table 55-1957. Glossary (continued)

Palette	The list of colors used by a graphic when an indexed colors format is used. The palette is stored in a color look up table and can be from one color up to the maximum of the size of the CLUT.
Panel	A TFT LCD containing an array of colored pixels.
Pixel	The basic graphical element on a TFT LCD panel. Can display a range of colors depending on the value of the red, green and blue values written to it. Normally arranged in a rectangular array.
RGB	A data format where the pixel values are stored using three components: Red, Green and Blue. DCU4 supports different variations of this format where different numbers of bits can be used to represent each of the components
Vertical blanking period	A time during the TFT LCD panel refresh cycle when no data is being written to the panel

Chapter 56
LCD Driver LCD64F6B

56.1 LCD Driver (LCD64F6B)

56.2 Information Specific to This Device

This section presents device-specific parameterization and customization information not specifically referenced in the remainder of this chapter.

56.2.1 Number of Front and Back Planes

Table 56-1. Number of Front and Back Planes

Parameter	Value
Number of front planes[1]	36 or 38 or 40
Number of back planes[2]	4 or 6 or 8

1. Software-configurable
2. Software-configurable

56.2.2 LCD Clock Selection

The following table shows the clocks selected by the LCDCR[LCDOCS] bit.

Table 56-2. LCD Clock Selection Based on LCDCR[LCDOCS]

Value of LCDCR[LCDOCS]	Clock selected
1	32 kHz OSC
0	128 kHz OSC

56.2.3 Settings during STANDBY mode

To keep the LCD driver shut down in STANDBY mode, the following settings are needed:

- LCDCR[LCDRST] = 0
- LCDCR[LCDRCS] = 0

To keep the LCD driver on (functioning) in STANDBY mode, the following settings are needed:

- LCDCR[LCDRST] = 1
- LCDCR[LCDRCS] = 1
- LCDCR[LCDOCS] = 0 or 1
  - If this field is 0, the LCD driver will operate from SIRC.
  - If this field is 1, the LCD driver will operate from SXOSC.

56.3 Introduction

This section introduces the LCD driver module.

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration chapter.

56.3.1 Overview

The LCD driver module has up to 64 frontplane drivers (*n*) and up to 8 backplane drivers (*m*) so that a maximum of 512 LCD segments are controllable. The actual implementation (*n,m*) depends on the device specification. Each segment is controlled by a corresponding bit in the LCD RAM. *m* multiplex modes (1/1, 1/2,…1/*m* duty), and three bias (1/1, 1/2, 1/3) methods are available. The V_0 voltage is the lowest level of the output waveform and V_3 becomes the highest level. All frontplane and backplane pins can be multiplexed with other Port functions.

The LCD driver system consists of five major sub-modules:

- Timing and Control – consists of registers and control logic for frame clock generation, bias voltage level select, frame duty select, contrast adjustment, backplane select and frontplane select/enable, remapping of backplane drivers to produce the required frame frequency and voltage waveforms.
- LCD RAM – contains the data to be displayed on the LCD. Data can be read from or written to the display RAM at any time.
- Frontplane Drivers – consists of *n* frontplane drivers.
- Backplane Drivers – consists of *m* backplane drivers.
- Voltage Generator – Based on reference voltage VDDE. It generates the voltage levels for the timing and control logic to produce the frontplane and backplane waveforms.

56.3.2 Block Diagram

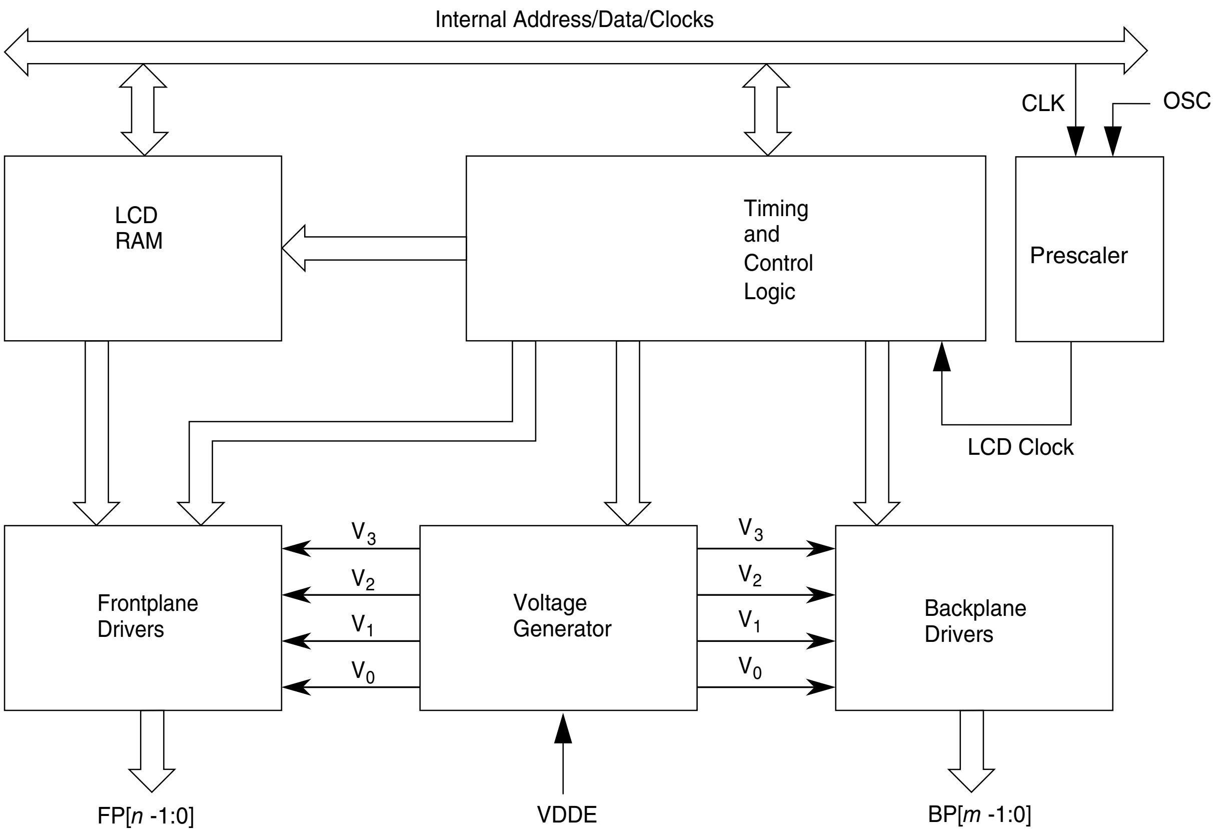

Figure 56-1. Block Diagram

56.3.3 Features

The LCD64F6B includes these distinctive features:

- Up to 64 frontplane drivers
  - Each frontplane has an individual enable bit
- Up to 8 backplane drivers
- Remapping of backplane drivers
- Programmable frame clock generator
- Programmable bias voltage level selector
- Programmable output current
- Selectable output current boost during transitions.
- Selectable LCD frame frequency interrupt event
- On-chip generation of four different output voltage levels
- Contrast adjustment by using Contrast adjustment phases
- Selectable continuous drive of LCD while in power down mode

56.3.4 Modes of Operation

The LCD64F6B module supports up to seven operation modes with different numbers of backplanes and different biasing levels. During power saving mode the LCD operation can be suspended under software control. Depending on the state of internal bits, the LCD can operate normally with source clock applied, or the LCD clock generation can be turned off and the LCD64F6B module enters a power conservation state.

This is a high level description only, detailed descriptions of operating modes are contained in later sections.

56.4 External Signal Description

Table 56-3. Signal Properties

Name	Port	Function	Reset	Pull Up
m Backplane Waveforms	BP[*m*-1:0]	Backplane waveform signals that connect directly to the pads	high impedance	
n Frontplane Waveforms	FP[*n*-1:0]	Frontplane waveform signals that connect directly to the pads	high impedance	
VDD33 Voltage	VDD33	LCD supply and reference voltage		
VSSE Voltage	VSSE	LCD ground voltage		

56.4.1 Detailed Signal Descriptions

Table 56-4. Interface A—Detailed Signal Descriptions

Signal	Description
BP[*m*-1:0]	This output signal vector represents the analog backplane waveforms of the LCD64F6B module and is connected directly to the corresponding pads.
FP[*n*-1:0]	This output signal vector represents the analog frontplane waveforms of the LCD64F6B module and is connected directly to the corresponding pads.
VDDE	Positive supply and reference voltage for the LCD waveform generation.
VSSE	Ground supply voltage for the LCD waveform generation.

56.5 Memory Map and Registers

This section describes the Memory map table and the register descriptions in address order.

LCD memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400B_E000	LCD Control Register (LCD_LCDCR)	32	R/W	0000_0000h	56.5.1/3230

Table continues on the next page...

LCD memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400B_E004	LCD Prescaler Control Register (LCD_LCDPCR)	32	R/W	0000_0000h	56.5.2/3232

R	NOF								0	0	LCDBPA		0	LCDBPS		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCD_LCDCR field descriptions

Field	Description
31 LCDEN	LCD Driver System Enable. 0 All frontplane and backplane pins are disabled. In addition, the LCD Driver is disabled and all LCD waveform generation clocks are stopped. 1 LCD Driver System is enabled. All FP[n-1:0] pins with ENFP[n-1] set, will output an LCD driver waveform. The BP[m-1:0] pins will output an LCD Driver waveform based on the settings of DUTY.
30 LCDRST	Continue to drive LCD display while stop/standby requested.Can be written only when LCDEN is cleared. See Section “Operation in Power Saving Modes” for details. 0 Stop LCD64F6B display driver system while stop/standby requested. 1 LCD display driver system operates normally while stop/standby requested.
29 LCDRCS	LCD Reference Clock Select.Can be written only when LCDEN is cleared.It controls the selection between oscillator clock and system clock. 0 System clock is selected. 1 scillator clock selected based on LCDOCS.
28–26 DUTY	LCD Duty Select. The DUTY bits select the duty (multiplex mode) of the LCD Driver system as shown in Table 56-23 . The multiplex mode should be changed only when LCD Driver is disabled, LCDEN is not set.
25 BIAS	BIAS Voltage Select.This bit selects the bias voltage levels during various LCD operating modes, as shown in Table 56-23
24 VLCDS	Reserved Can be written only when LCDEN is cleared. See Operation in Power Saving Modes 0 No effect. 1 No effect.
23–22 PWR	LCD Power mode The PWR bits select the output current and have a direct impact on the power consumption and drive capability of the LCD64F6B module. Table 56-24 lists the possible selections.
21 BSTEN	LCD output current boost enable Since the LCD appears like a capacitance to the driver it is sometimes useful to boost the output current during transitions to increase the slew rate of the driver. 0 No output current boost available. 1 Output current boost during transitions according to the BSTSEL bit.
20 BSTSEL	LCD output current boost select The BSTSEL bit sets the multiplier for the output current boost. If the BSTEN bit is set, the output current is boosted during transitions in the following way: 0 Current boosting by a factor of 8. 1 Current boosting by a factor of 16.
19 BSTAO	LCD Boost always on.If set, the selected by BST and enabled by BSTEN boost current is always on and not only during the time frame generated by the state machine 0 The Boost always on feature is disabled. 1 The Boost always on feature is enabled.
18 LCDOCS	LCD OSC Clock Select. Can be written only when LCDEN is cleared..It selects between oscillator clocks. 0 128Khz Slow Internal RC Oscillator Clock is selected. 1 32Khz External Oscillator clock is selected.
17 LCDINT	LCD interrupt enable. 0 Interrupt request is disabled. 1 Interrupt will be requested whenever EOF is set.

Table continues on the next page...

LCD_LCDCR field descriptions (continued)

Field	Description
16 EOF	End of frame interrupt flag. End of frame interrupt flag bit is set every time when NOF frames have been executed while LCDEN is set. This flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (LCDINT = 1), EOF causes an interrupt request. 0 Defined via NOF bits frames have not been executed yet. 1 Defined via NOF bits frames have been executed.
15–8 NOF	Number of frames.The number of frames bits determine how many frames are counted until an interrupt will be requested. The possible number of frames are: 0x00 An interrupt is requested at the end of every frame 0x01 An interrupt is requested at the end of every second frame. .... and so on up to 0xFF An interrupt is requested at the end of every 256th frame
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 LCDBPA	Backplane Adding. If set, the backplanes, which are not available in standard configuration, will be mapped on frontplanes as shown in Table 469. Hence, up to six backplanes can be used to drive LCD displays.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 LCDBPS	Backplane Shifting. Using these bits, backplanes will be swapped with frontplanes as shown in Table 469.

56.5.2 LCD Prescaler Control Register (LCD_LCDPCR)

Address: 400B_E000h base + 4h offset = 400B_E004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				LCLK				0																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCD_LCDPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–24 LCLK	LCD Clock Prescaler. The LCD Clock Prescaler bits determine the clock divider value to produce the LCD Clock Frequency. For detailed description of the correlation between LCD Clock Prescaler bits and the divider value please refer to Table 56-21. LCD Clock Prescaler bits should be changed only when LCD Driver is disabled, LCDEN is not set.
23–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.5.3 LCD Contrast Control Register (LCD_LCDCCR)

Address: 400B_E000h base + 8h offset = 400B_E008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	CCEN	Reserved				LCC										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCD_LCDCCR field descriptions

Field	Description
31 CCEN	LCD Contrast Control Enable. 0 The Contrast Control is disabled. 1 The Contrast Control is enabled. The length of the contrast phase depends on the bits LCC.
30–27 Reserved	This field is reserved. Reserved.
26–16 LCC	LCD Contrast Control. The Contrast Control bits determine the width of the contrast phase. 0x7FF=Contrast Phase lasts the whole duty cycle. 0x000=Contrast Phase has no duration what results in highest contrast.
15–0 Reserved	This field is reserved. Reserved.

56.5.4 LCD Frontplane Enable Register 0 (LCD_ENFPR0)

Address: 400B_E000h base + 10h offset = 400B_E010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	ENFP[31:0]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCD_ENFPR0 field descriptions

Field	Description
31–0 ENFP[31:0]	Frontplane Output Enable. The ENFP[31:0] bits enable the frontplane driver outputs. If LCDEN = 0, these bits have no effect on the state of the I/O pins. It is recommended to set ENFP[31:0] bits before LCDEN is set. 1 Frontplane driver output enabled on FP[31:0]. 0 Frontplane driver output disabled on FP[31:0].

56.5.5 LCD Frontplane Enable Register 1 (LCD_ENFPR1)

Address: 400B_E000h base + 14h offset = 400B_E014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

56.6 Functional Description

This section describes frontplane, backplane, LCD System During Reset, LCD clock and frame frequency, contrast adjustment, LCD driver system enable and frontplane enable sequencing.

56.6.1 Frontplane, Backplane, and LCD System During Reset

During a reset the following conditions exist:

- All frontplane enable bits, ENFP[*n*-1:0] are cleared and the ON/OFF control for the display, the LCDEN bit is cleared, thereby forcing all frontplane and backplane driver outputs to the high impedance state. The pin state during reset is defined by the port control module.
- The LCD64F6B system is configured in the default mode, 1/1 duty and 1/1 bias, that means only BP0 is used, system clock as reference.

56.6.2 LCD Clock and Frame Frequency

The frequency of the clock and the clock divider determine the LCD Clock Frequency. The input clock for the prescaler can be selected by LCDRCS bit. The divider is set by the LCD Clock Prescaler bits in the LCD Prescaler Control Register as shown in the following table.

Table 56-21. Clock Divider

LCLK	Divider
0000	480
0001	2 * 480
0010	2^2 * 480
0011	2^3 * 480
0100	2^4 * 480
0101	2^5 * 480
0110	2^6 * 480
0111	2^7 * 480
1000	2^8 * 480
1001	2^9 * 480
1010	2^{10} * 480
1011	2^{11} * 480
1100	2^{12} * 480
1101	2^{13} * 480
1110	2^{14} * 480
1111	2^{15} * 480

The following formula may be used to calculate the LCD frame frequency:

$$\mathrm{LCDFrameFrequency}(\mathrm{Hz}) = \left[\frac{\mathrm{OSCCLK}(\mathrm{Hz})}{\mathrm{Divider}}\right]$$

Example: Clock = 16 MHz, Prescaler = 1010;

$$\left[\frac{16 \bullet 10^6}{2^{10} \bullet 480}\right] \approx 33\mathrm{Hz}$$

Note

A "Frame" is the full refresh cycle of the display. See LCD Waveform Examples for waveform illustrations.

56.6.3 Contrast Adjustment

The LCD Driver module offers two different ways to adjust contrast:

56.6.3.1 Adjusting the supply voltage (VDDE)

The VDDE voltage is directly used as reference and source to drive the LCD segments. The contrast could be adjusted by altering the voltage VDDE, but be aware that this voltage is used for the padring also.

56.6.3.2 Adding Contrast Adjustment Phases

Another way to adjust the contrast is to add another phase to the refresh cycle which keeps the voltage the same on all frontplane and backplane electrodes (V_{SS} in this case). This will contribute towards lowering the V_{ONRMS} and V_{OFFRMS} voltages over the segment. For this reason, the whole frame is divided into steps. The value from the Contrast Control register (LCC) determines how many of these steps are taken by the contrast phase. Whenever the length of the contrast adjustment phase is changed, the length of the other phases is automatically changed to ensure the frame length remains the same.

Example: A value of 256 in the Contrast Control (LCC) register will force the contrast phase to take approximately a 256/2047 of the length of the whole frame.

The figure below shows an example of waveform with 1/1 duty and 1/1 bias ratios with the additional contrast adjustment phases

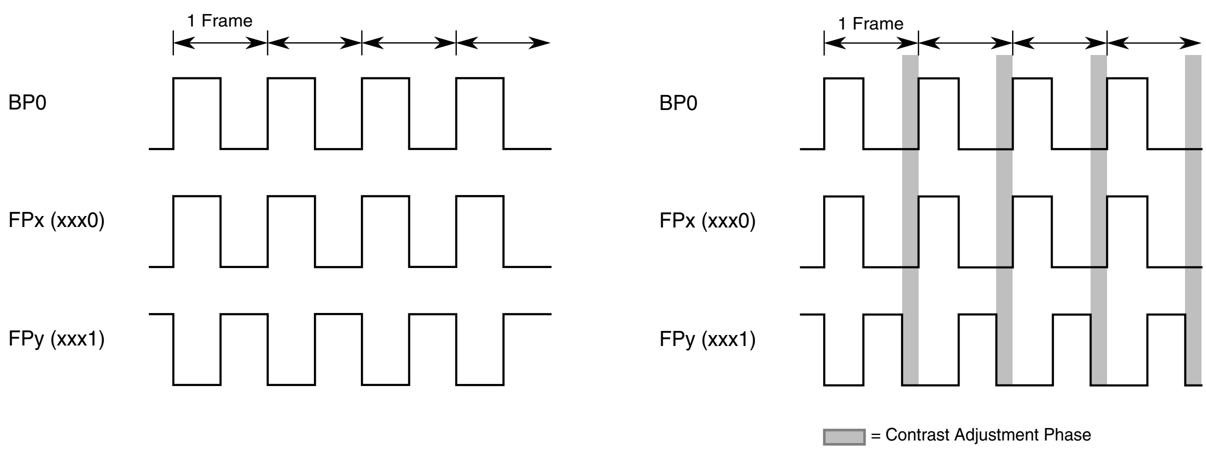

Figure 56-17. Contrast Adjustment Phases

Note

RMS stands for root mean square and is a statistical measure of the magnitude of a varying quantity. It is calculated with the formula:

$$V_{\mathrm{RMS}} = \sqrt{\frac{\int_0^T V^2 \mathrm{dt}}{T}}$$

56.6.4 LCD RAM

For a segment on the LCD to be displayed, data must be written to the LCD RAM which is shown in Memory Map and Register Definition. The bits in the LCD RAM correspond to the segments that are driven by the frontplane and backplane drivers. Writing a '1' to a given location will result in the corresponding display segment being driven with a differential RMS voltage, based on selected reference, necessary to turn the segment ON when the LCDEN bit is set and the corresponding ENFP[*n*-1:0] bit is set. Writing a '0' to a given location will result in the corresponding display segment being driven with a differential RMS voltage necessary to turn the segment OFF. The LCD RAM is a dual port RAM that interfaces with the internal address and data buses of the MCU. It is possible to read from LCD RAM locations for scrolling purposes. Writing or reading of the LCDEN bit does not change the contents of the LCD RAM. After a reset, the LCD RAM contents will be cleared.

56.6.5 LCD Driver System Enable and Frontplane Enable Sequencing

If LCDEN = 0 (LCD Driver System disabled) and the frontplane enable bit, ENFP[*n*-1:0], is set, the frontplane driver waveform will not appear on the output until LCDEN is set. If LCDEN = 1 (LCD Driver System enabled), the frontplane driver waveform will appear on the output as soon as the corresponding frontplane enable bit, ENFP[*n*-1:0], in the registers ENFPR0 and ENFPR1 is set.

56.6.6 LCD Driver Backplane Remapping

The backplane and frontplane pins can be remapped/swapped using LCDBPS and LCDBPA. While LCDBPA adds the non available backplane waveforms onto FP pins, LCDBPS does a swapping of backplanes waveforms with frontplanes waveforms on selected pins. The swapping of LCDBPS depends on the availability of Frontplane pins FP[n-1:0]. If the number of frontplanes n implemented is not sufficient no remapping will occur. See the following table for details.

Table 56-22. Backplane Remapping

LCDBPS	Condition: FP[n-1:0]	Remapping LCDBPA[1:0]=00 or LCDBPA[1:0]=11 BP[m-1:0]	Remapping LCDBPA[1:0]=01BP[m-1:0]	Remapping LCDBPA[1:0]=10BP[m-1:0]
000		no remapping	FP[5-m:0] <- BP[5:m] if m=6 no remapping	FP[7-m:0] <- BP[7:m] if m=8 no remapping
001		BP[m-1:0] <- FP[m-1+4:4] FP[m-1+4:4] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+4:4] FP[5+4:4] <- BP[5:0]	BP[m-1:0] <- FP[m-1+4:4] FP[7+4:4] <- BP[7:0]
010		BP[m-1:0] <- FP[m-1+12:12] FP[m-1+12:12] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+12:12] FP[5+12:12] <- BP[5:0]	BP[m-1:0] <- FP[m-1+12:12] FP[7+12:12] <- BP[7:0]
011		BP[m-1:0] <- FP[m-1+20:20] FP[m-1+20:20] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+20:20] FP[5+20:20] <- BP[5:0]	BP[m-1:0] <- FP[m-1+20:20] FP[7+20:20] <- BP[7:0]
100	n=36 or n>36	BP[m-1:0] <- FP[m-1+28:28] FP[m-1+28:28] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+28:28] FP[5+28:28] <- BP[5:0]	BP[m-1:0] <- FP[m-1+28:28] FP[7+28:28] <- BP[7:0]
101	n=44 or n>44	BP[m-1:0] <- FP[m-1+36:36] FP[m-1+36:36] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+36:36] FP[5+36:36] <- BP[5:0]	BP[m-1:0] <- FP[m-1+36:36] FP[7+36:36] <- BP[7:0]
110	n=52 or n>52	BP[m-1:0] <- FP[m-1+44:44] FP[m-1+44:44] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+44:44] FP[5+44:44] <- BP[5:0]	BP[m-1:0] <- FP[m-1+44:44] FP[7+44:44] <- BP[7:0]
111	n=60 or n>60	BP[m-1:0] <- FP[m-1+52:52] FP[m-1+52:52] <- BP[m-1:0]	BP[m-1:0] <- FP[m-1+52:52] FP[5+52:52] <- BP[5:0]	BP[m-1:0] <- FP[m-1+52:52] FP[7+52:52] <- BP[7:0]

Examples:

1. 40 (n=40) Frontplanes and 4 (m=4) backplanes are implemented. LCDBPS is set to 000 and LCDBPA is set to 01

   Frontplanes FP[39:2] and BP[3:0] will stay the same, but FP[1:0] pins will controlled by BP[5:4] functionality.

2. 40 (n=40) Frontplanes and 4 (m=4) backplanes are implemented. LCDBPS is set to 010 and LCDBPA is set to 00

   Frontplanes FP[39:16] and FP[11:0] will stay the same, but FP[15:12] pins are swapped with BP[3:0].

3. 40 (n=40) Frontplanes and 4 (m=4) backplanes are implemented. LCDBPS is set to 010 and LCDBPA is set to 01

   Frontplanes FP[39:18] and FP[11:0] will stay the same. FP[15:12] pins are swapped with BP[3:0]. FP[17:16] is replaced by BP[5:4] functionality.

4. 40 (n=40) Frontplanes and 4 (m=4) backplanes are implemented. LCDBPS is set to 101 and LCDBPA is set to 01

No remapping: Frontplanes FP[39:0] and BP[3:0] will stay the same, because condition n>=44 is not fulfilled.

56.6.7 LCD Bias and Modes of Operation

The LCD64F6B driver has seven modes of operation:

- 1/1 Duty (1 backplane), 1/1 Bias (2 voltage levels)
- 1/2 Duty (2 backplanes), 1/2 Bias (3 voltage levels)
- 1/2 Duty (2 backplanes), 1/3 Bias (4 voltage levels)
- 1/3 Duty (3 backplanes), 1/3 Bias (4 voltage levels)
- 1/4 Duty (4 backplanes), 1/3 Bias (4 voltage levels)
- 1/5 Duty (5 backplanes), 1/3 Bias (4 voltage levels)
- 1/6 Duty (6 backplanes), 1/3 Bias (4 voltage levels)
- 1/8 Duty (8 backplanes), 1/3 Bias (4 voltage levels)

The voltage levels required for the different operating modes are generated internally based on selected reference voltage. VDDE as used as reference and supply. Changing VDDE alters the differential RMS voltage across the segments in the ON and OFF states, thereby can change the display contrast.

The backplane waveforms are continuous and repetitive every frame. They are fixed within each operating mode and are not affected by the data in the LCD RAM.

The frontplane waveforms generated are dependent on the state (ON or OFF) of the LCD segments as defined in the LCD RAM. The LCD driver hardware uses the data in the LCD RAM to construct the frontplane waveform to create a differential RMS voltage necessary to turn the segment ON or OFF.

The LCD duty is decided by the DUTY bits in the LCD Control Register (LCDCR). The number of bias voltage levels is determined by the BIAS bit in the LCDCR. The following table summarizes the Multiplex modes (duties) and the bias voltage levels that can be selected for each multiplex mode (duty). The backplane pins have their corresponding backplane waveform output BP[*m*-1:0] in high impedance state when in the OFF state as indicated in the following table. In the OFF state the corresponding pins BP[*m*-1:0]can be used for other functionality.

Table 56-23. LCD Duty and Bias

<table>
<tr><th></th><th>LCDCR Register</th><th colspan="8">Backplanes</th><th colspan="2">Bias Level</th></tr>

56.6.8 Operation in Power Saving Modes

56.6.8.1 Operation in STOP mode

The LCD64F6B system operation during STOP mode is controlled by the LCDRST bit in the LCD Control Register (LCDCR).

If the LCD64F6B is requested to enter STOP mode and LCDRST is cleared while LCDEN is set the LCD waveform generation clocks are stopped and the LCD64F6B drivers pull down to ground those frontplane and backplane pins that were enabled before entering STOP mode.The contents of the LCD RAM and the LCD registers retain the values they had prior to entering stop mode.

If LCDRST is set while LCDEN is set and the LCD64F6B is requested to enter STOP mode the LCD waveform generation is continued.

56.6.8.2 Operation in LPSTOP Mode

The LCD64F6B system operation during LPSTOP Modemode is controlled by the LCDRST bit in the LCD Control Register (LCDCR).

If the LCD64F6B is not powered down by the system, and is requested to enter LPSTOP Modemode and LCDRST is cleared while LCDEN is set the LCD waveform generation clocks are stopped and the LCD64F6B drivers pull down to ground those frontplane and

backplane pins that were enabled before entering LPSTOP Modemode.The contents of the LCD RAM and the LCD registers retain the values they had prior to entering LPSTOP Modemode.

If the LCD64F6B is not powered down by the system, and is requested to enter LPSTOP Modemode and LCDRST is set while LCDEN is set the LCD waveform generation is continued.

Note

The user needs to take care that the system keeps the clock applied to the running LCD64F6B module during all modes where it is enabled. If no clock is applied while the LCD64F6B module is running the LCD could be damaged.

56.6.9 Other Power Saving

The LCD64F6B has features to adjust the frontplane & backplane drive strength and to boost the drive strength while the planes are switching.

56.6.9.1 LCD Reference Clock Select

Using LCDRCS the LCD reference clock can be selected. If LCDRCS is cleared, the system clock is applied as reference clock to the prescaler input. If LCDRCS is set, the source clock for LCD Driver system (prescaler input) is SXOSC clock. Selecting the lower power consuming clock of both as reference clock for the prescaler input can save power consumption.

56.6.9.2 Boost at Switching

Since the LCD appears like a capacitance to the driver it is sometimes useful to boost the output current during transitions to increase the slew rate of the driver. If boosting is enabled, the drive strength capability is increased a little ahead in time when the planes are switching, and reduced again to normal drive after a certain time. To enable the boosting BSTEN need to be set. If BSTEN is not set, standard drive strength is used.

Using the BST bit if BSTEN is set, LCD output current magnification (boost) can be selected. Available is 8 times boosting, when BST is deasserted and 16 times boosting when BST is asserted.

The selected boost via BST bit can be switched to be always on by setting BSTAO, if BSTEN is set.

56.6.9.3 Standard Drive Selection

The output current has a direct impact on the power consumption and drive capability of the LCD64F6B module. The PWR bits select the output current height and can be used to influence power consumption and drive strength. The following table lists the possible selections of PWR.

Table 56-24. Output Current Selection (PWR)

PWR	Current
00	Standard Current
01	2 * Standard Current
10	3 * Standard Current
11	4 * Standard Current

56.6.9.4 Usage Recommendation

It is recommended to start with maximum output current and maximum enabled boosting. As long as the LCD is fully functional in all environments a reduction of Output Current and boosting can be done.

When reducing the Output Current (PWR), the power consumption of the LCD module and the maximum switching current of the planes is reduced.

When reducing or disabling the boosting (BST,BSTEN), the output current, while planes are switching, is reduced.

The user can select any combination of PWR, BST, BSTEN, BSTAO to what fit his needs best. The following figure gives an overview what is the impact when taking advance of Boost at Switching and Standard Drive Selection.

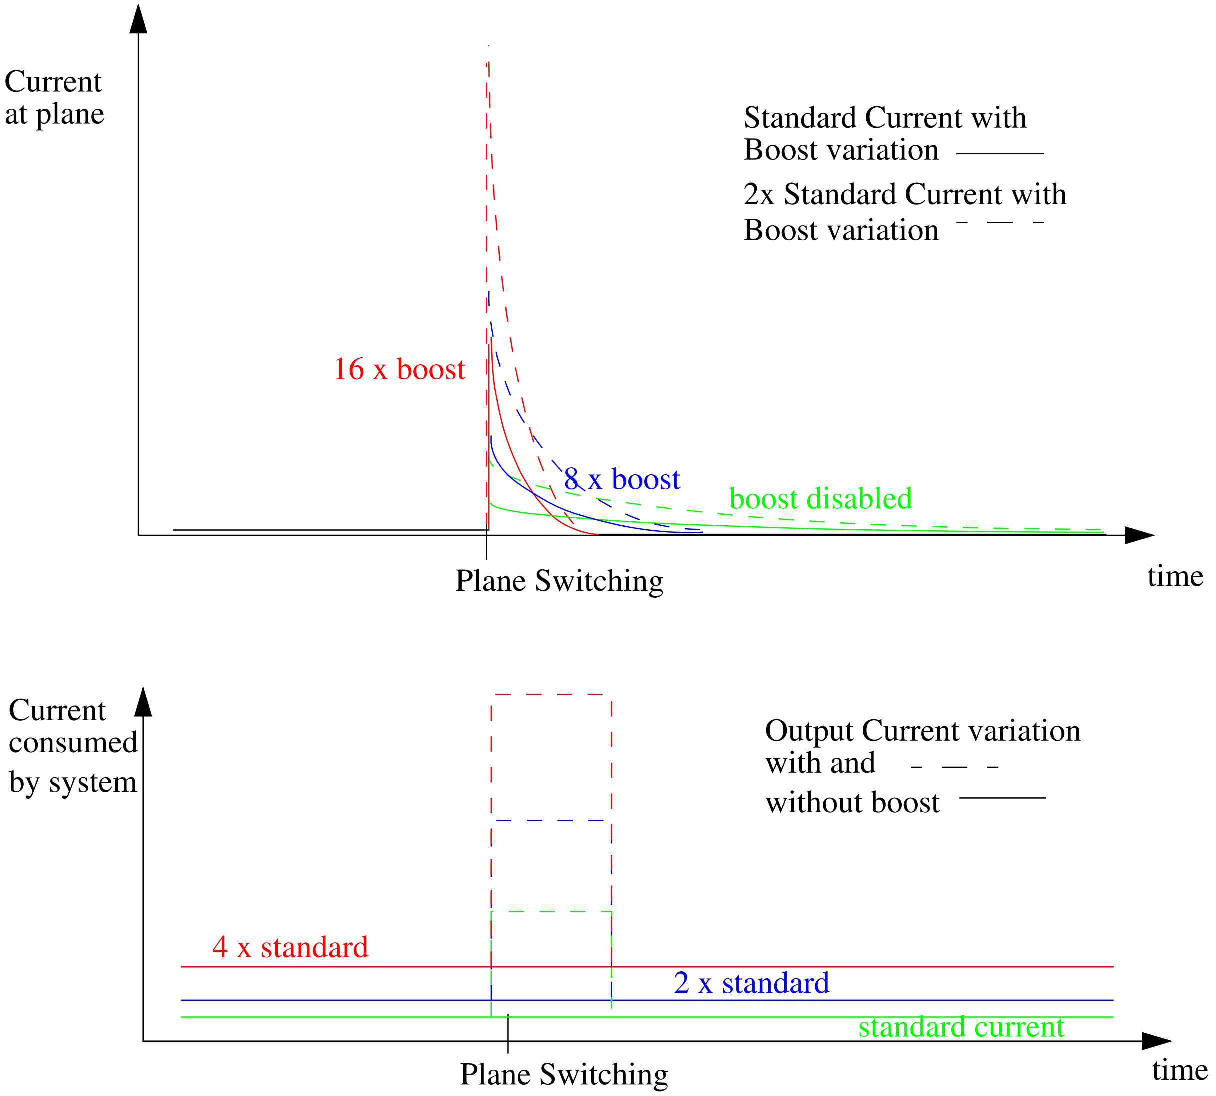

Figure 56-18. PWR, BST, BSTEN Example Diagram

56.6.10 Interrupts

This section describes all interrupts originated by LCD64F6B.

56.6.10.1 EOF Interrupt

LCDEN must be set to enable the interrupt at end of frame feature. Every time a frame generation was completed a counter is decremented by 1. If the counter reaches zero End of Frame interrupt Flag (EOF) bit is set and the counter is reset to NOF. The counter is reset to request interrupt at the end of every frame, as if NOF would be 0x00, if LCDEN is asserted while the LCD is off.

The EOF flag can only be cleared by writing a 1. Writing a 0 has no effect. If enabled (LCDINT = 1), EOF causes an interrupt request. The number of frames (NOF) bits determine how many frames are count until EOF flag is set. The possible number of frames are:

NOF= 0x00: An interrupt is requested at the end of every frame.

NOF= 0x01: An interrupt is requested at the end of every second frame.

NOF= 0x02: An interrupt is requested at the end of every third frame.

…

NOF= 0xFF: An interrupt is requested at the end of every 256th frame.

56.7 LCD Waveform Examples

The following figures show the timing examples of the LCD output waveforms for the available modes of operation. The contrast control is disabled in all examples (CCEN = 0 in LCDCCR). Reference voltage is VDDE.

56.7.1 1/1 Duty Multiplexed with 1/1 Bias Mode

Duty = 1/1:DUTY = 000

Bias = 1/1:BIAS = 0 or BIAS = 1

$V_0 = V_1 =$ VSSE $V_2 = V_3 =$ VDDE

- Only BP0 is used, a maximum of 64 segments are displayed.

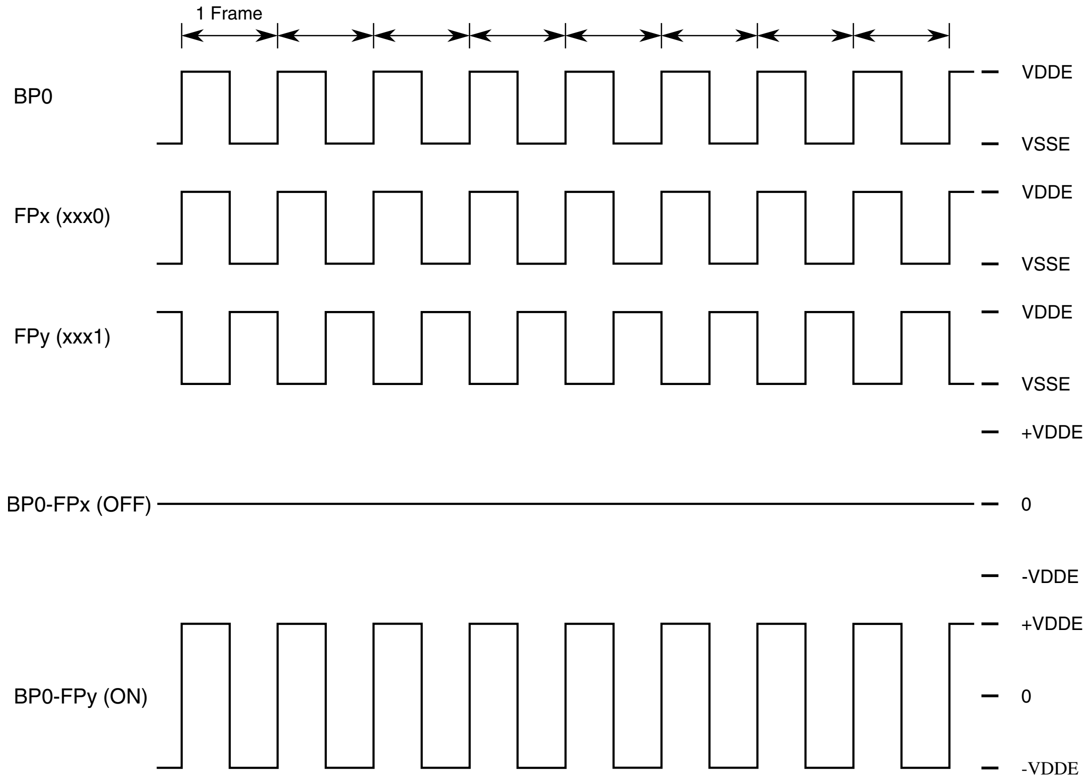

Figure 56-19. 1/1 Duty and 1/1 Bias

56.7.2 1/2 Duty Multiplexed with 1/2 Bias Mode

Duty = 1/2:DUTY = 001

Bias = 1/2:BIAS = 0

V_0 = VSSE, V_1 = VDDE * 1/3, V_2 = VDDE * 2/3, V_3 = VDDE

- Only BP0 and BP1 are used, a maximum of 128 segments are displayed.

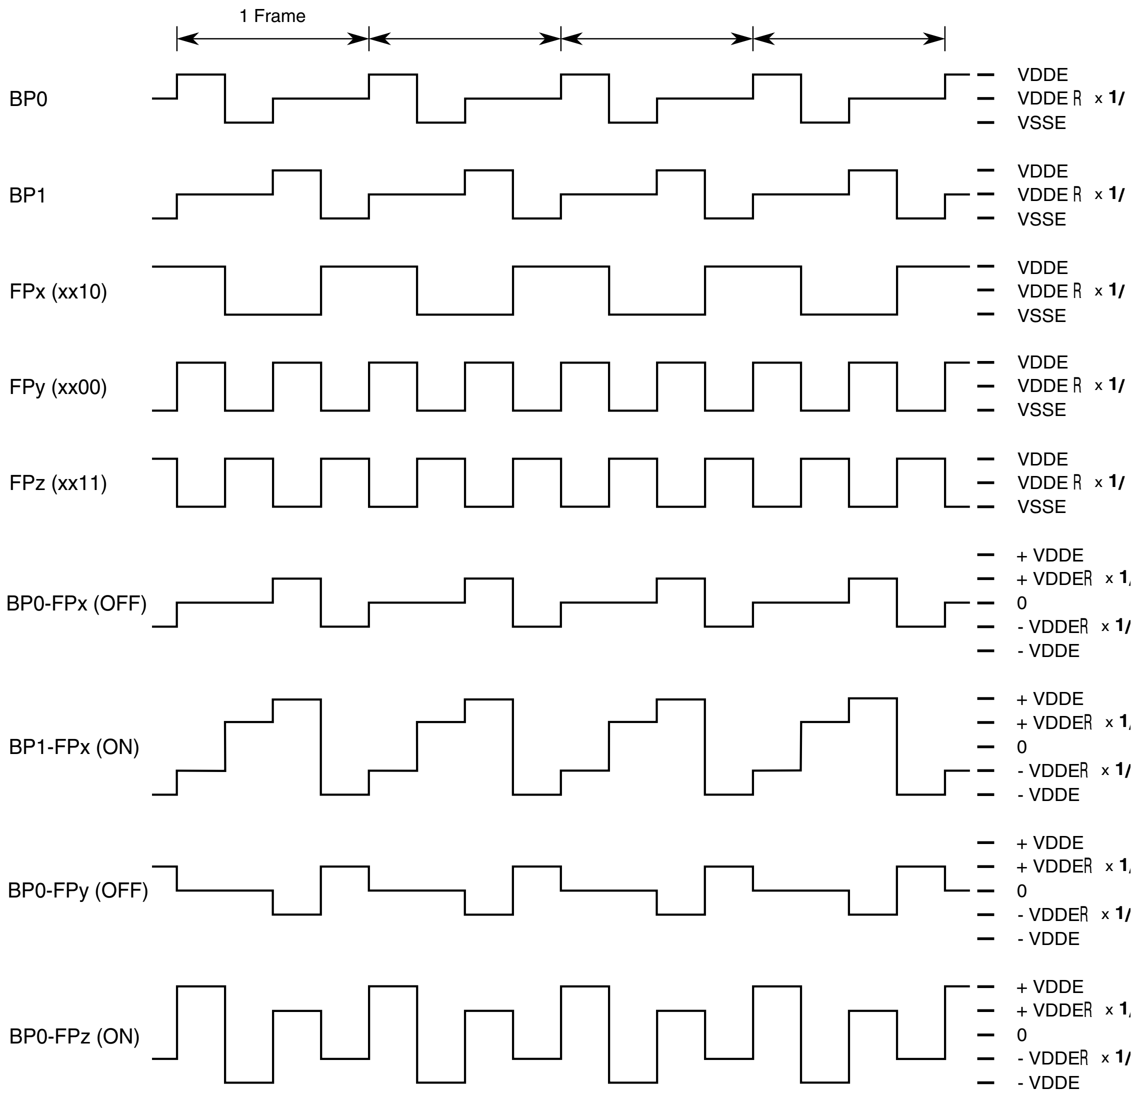

Figure 56-20. 1/2 Duty and 1/2 Bias

56.7.3 1/2 Duty Multiplexed with 1/3 Bias Mode

Duty = 1/2:DUTY = 001

Bias = 1/3:BIAS = 1

V_0 = VSSE, V_1 = VDDE * 1/3, V_2 = VDDE * 2/3, V_3 = VDDE

- Only BP0 and BP1 are used, a maximum of 128 segments are displayed.

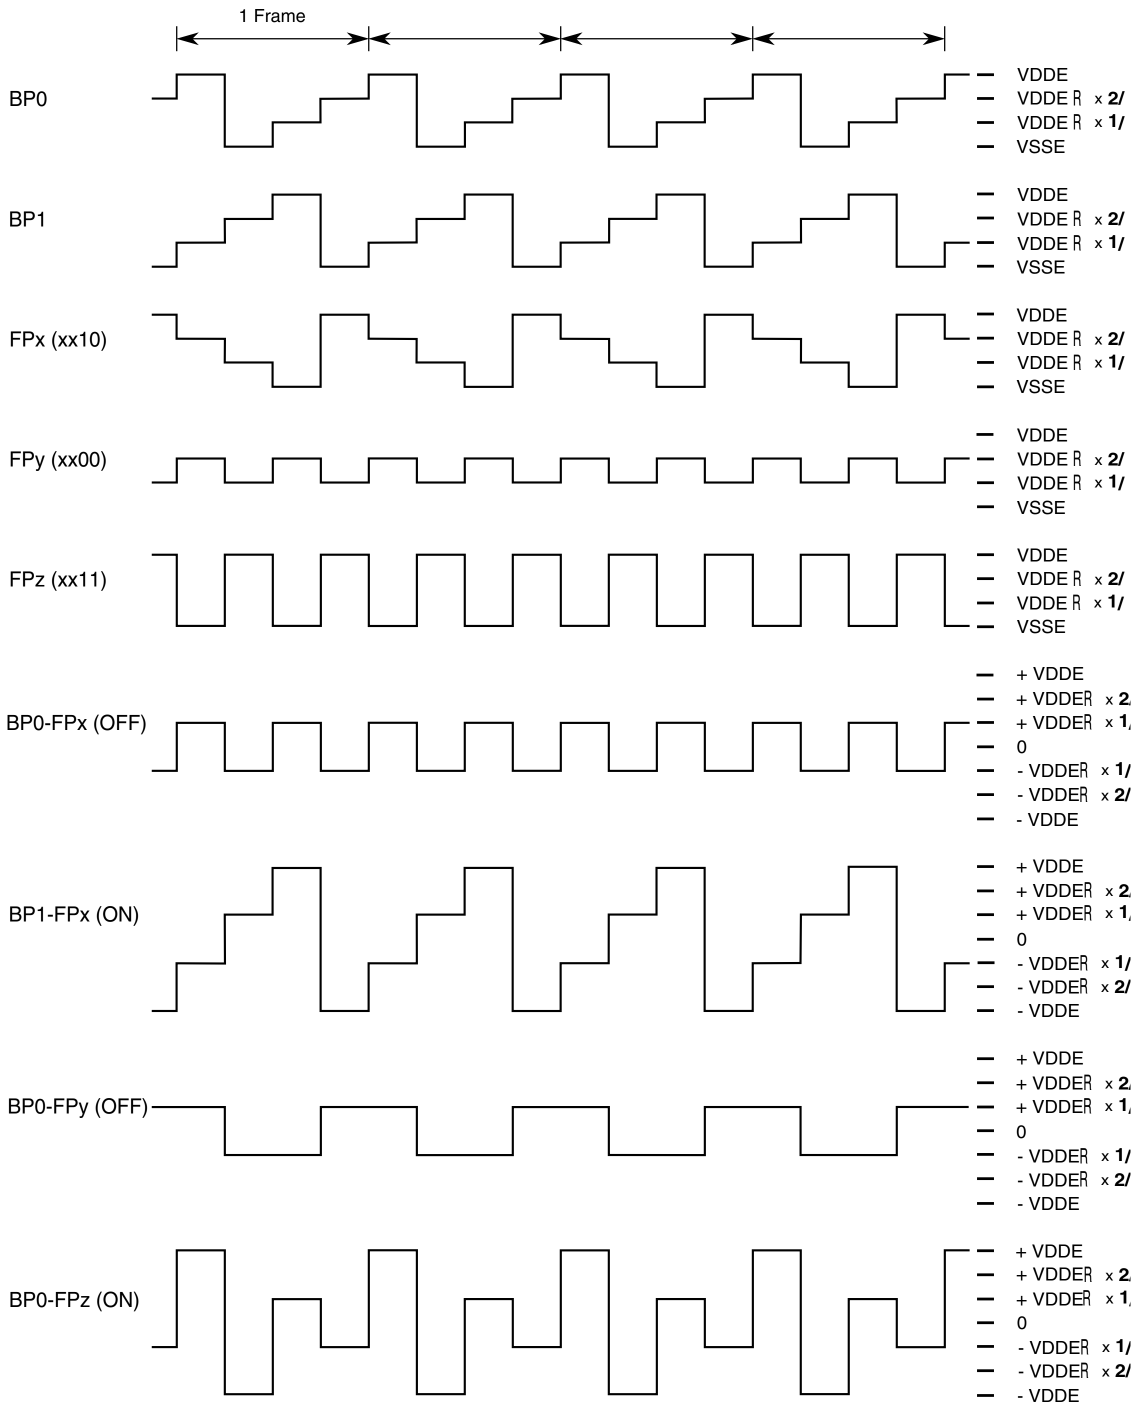

Figure 56-21. 1/2 Duty and 1/3 Bias

56.7.4 1/3 Duty multiplexed with 1/3 Bias mode

Duty = 1/3:DUTY = 010

Bias = 1/3:BIAS = 0 or BIAS = 1

V_0 = VSSE, V_1 = VDDE * 1/3, V_2 = VDDE * 2/3, V_3 = VDDE

- Only BP0, BP1 and BP2 are used, a maximum of 192 segments are displayed.

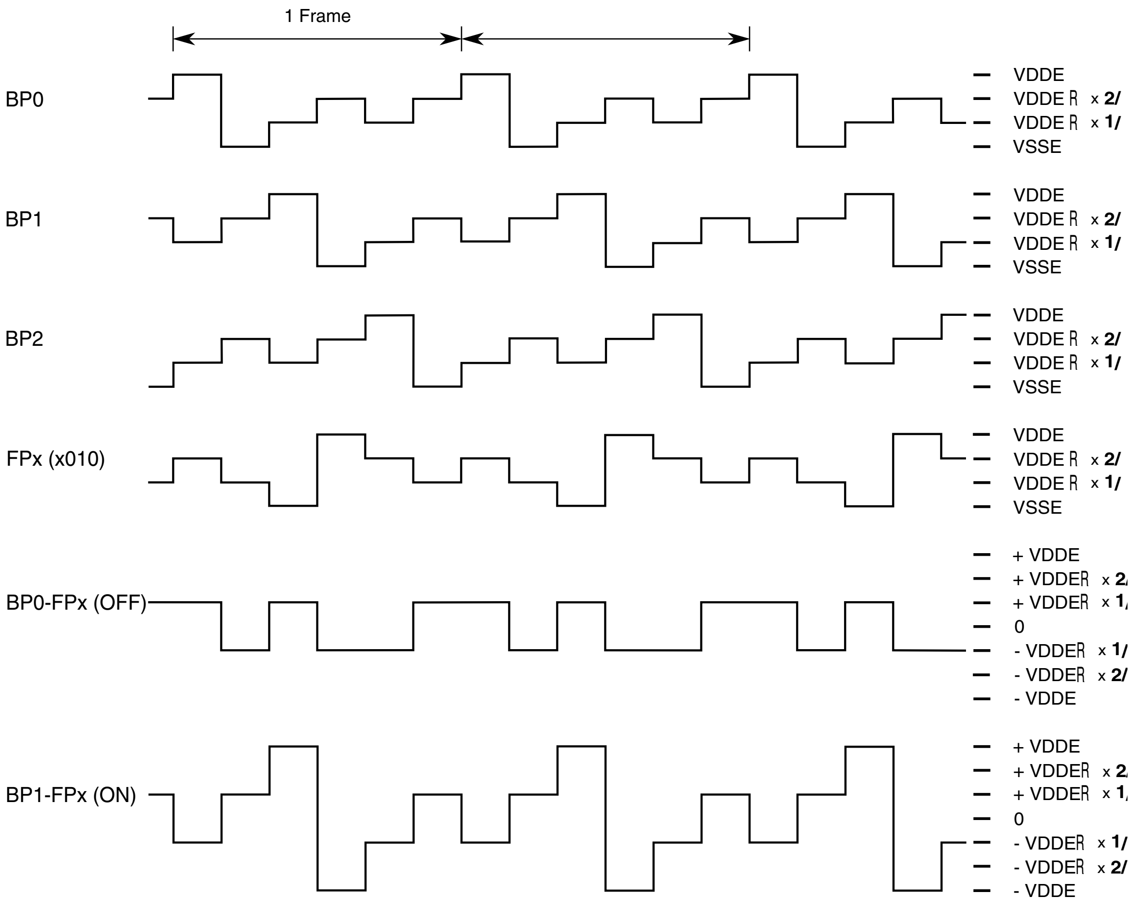

Figure 56-22. 1/3 Duty and 1/3 Bias

56.7.5 1/4 Duty multiplexed with 1/3 Bias mode

Duty = 1/4:DUTY = 011

Bias = 1/3:BIAS = 0 or BIAS = 1

V_0 = VSSE, V_1 = VDDE * 1/3, V_2 = VDDE * 2/3, V_3 = VDDE

- BP4 and BP5 are not used, a maximum of 256 segments are displayed.

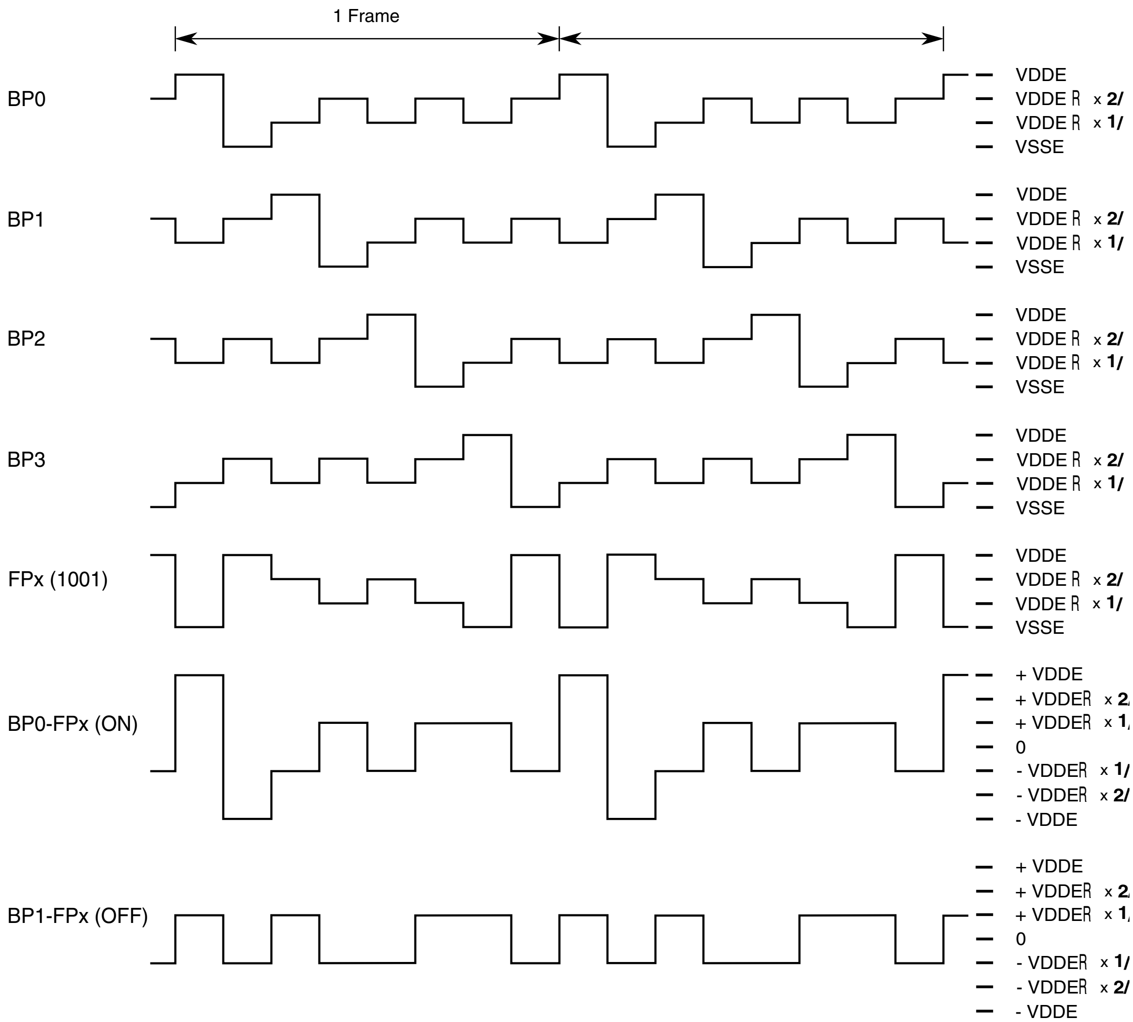

Figure 56-23. 1/4 Duty and 1/3 Bias

56.7.6 1/5 Duty multiplexed with 1/3 Bias

Duty = 1/5:DUTY = 100

Bias = 1/3:BIAS = 0 or BIAS = 1

V_0 = VSSE, V_1 = VDDE * 1/3, V_2 = VDDE * 2/3, V_3 = VDDE

- BP5 is not used, a maximum of 320 segments are displayed.

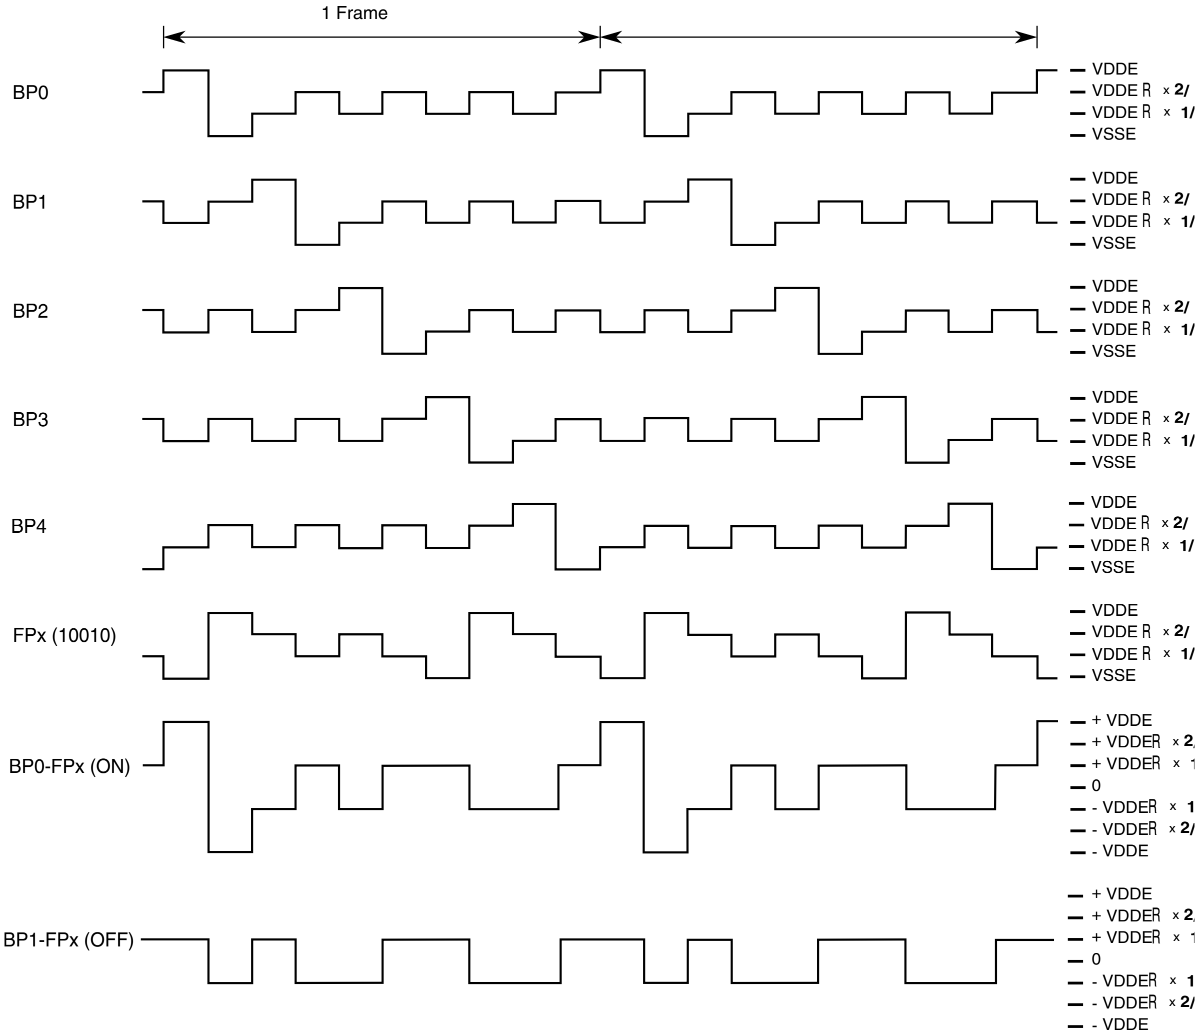

Figure 56-24. 1/5 Duty and 1/3 Bias

56.7.7 1/6 Duty multiplexed with 1/3 Bias mode

Duty = 1/5:DUTY = 101

Bias = 1/3:BIAS = 0 or BIAS = 1

V_0 = VSSE, V_1 = VDDE * 1/3, V_2 = VDDE * 2/3, V_3 = VDDE

- All backplanes are used, a maximum of 384 segments are displayed.

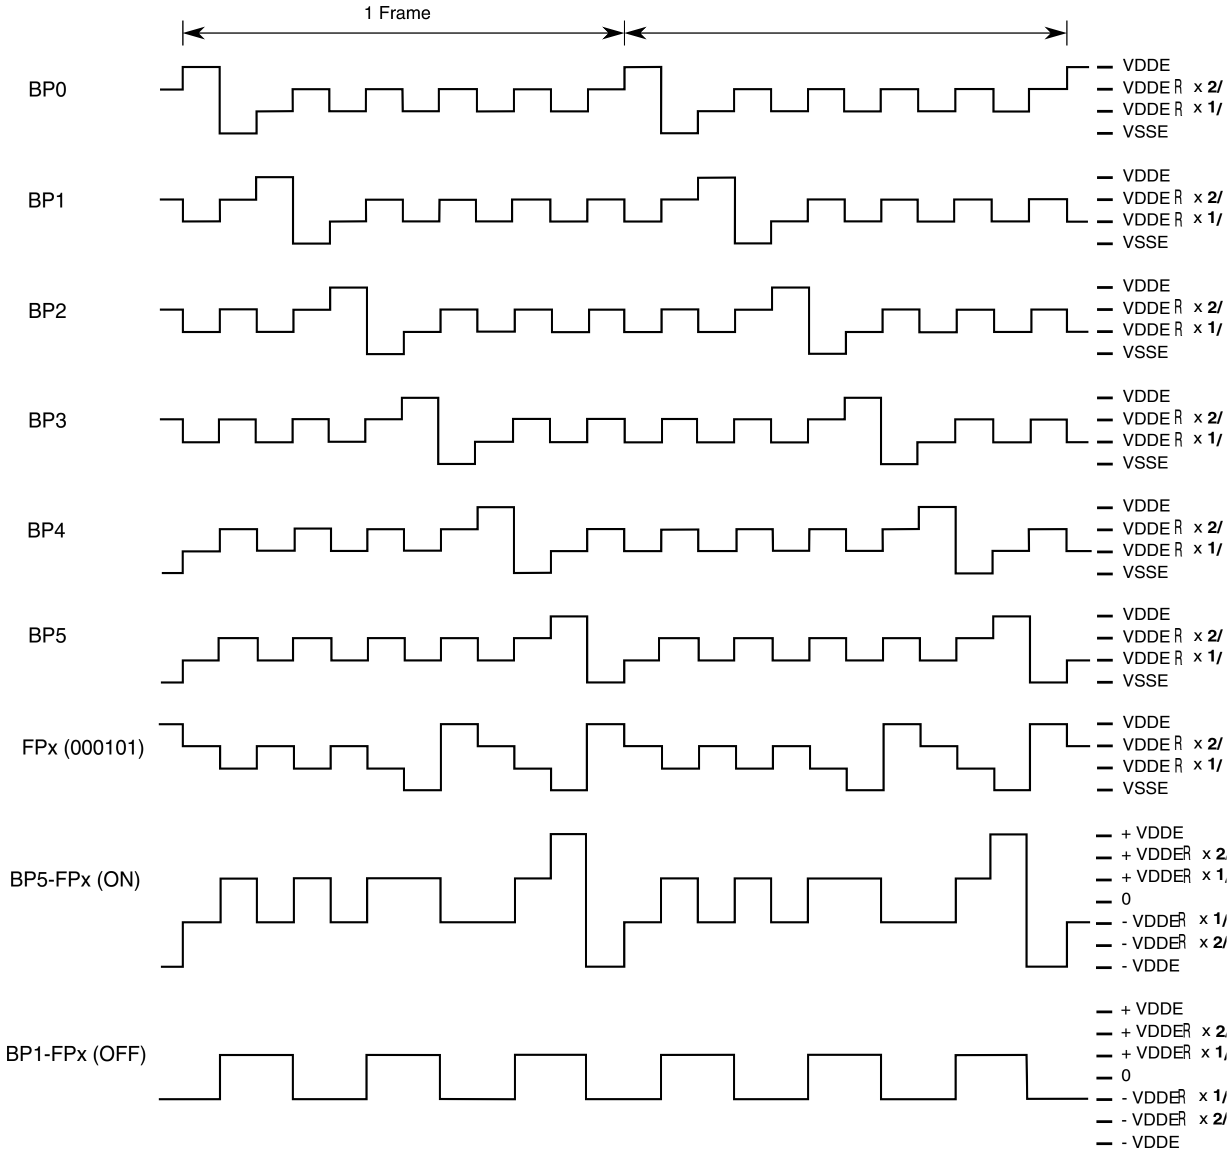

Figure 56-25. 1/6 Duty and 1/3 Bias

56.8 Initialization Information

This is a step-wise example instruction for initializing. The initial values of all registers are the reset values.

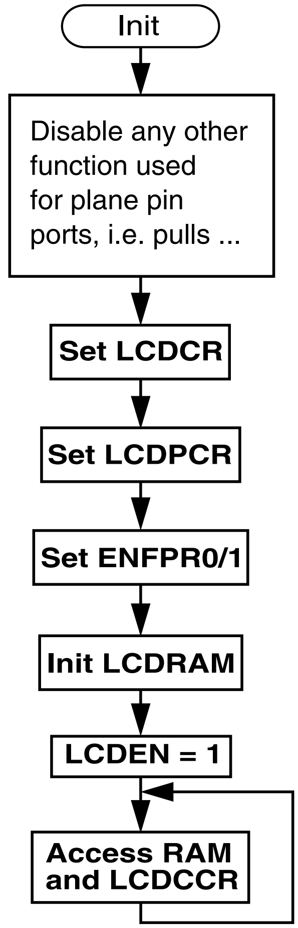

Figure 56-26. Example Initialization Diagram

Chapter 57
Video-In VIU3

57.1 Block Diagram

The figure below shows a block diagram of the Video-In 3 (VIU3).

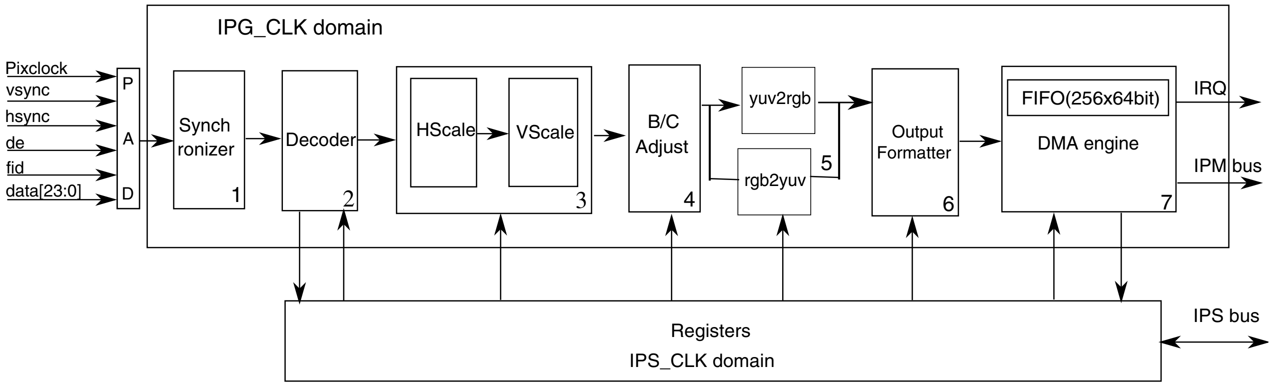

Figure 57-1. VIU3 Block Diagram

57.2 Features

- Supports from QVGA to XVGA input/output resolution
- 8-bit ITU656 video input[1]
- RGB888/RGB666/RGB565 parallel input
- RGB888 input with one color component transferred per clock
- 24-bit YUV parallel input from analog video decoder
- Up to 1/8 video down-scaling on horizontal and vertical direction
- Up to 2/1 horizontal video up-scaling
- Horizontal mirroring
- Brightness/contrast adjust
- YUV to RGB 888/565 conversion
- RGB to YUV conversion when input is RGB

1. When down scaling and/or B/C adjust is enabled, the two LSB's of the 10-bit input are ignored.

- Simple de-interlace function (weaving) for interlaced or pseudo interlaced video input
- Internal DMA engine for transferring data from FIFO to system memory

57.3 Video Input Signal Mapping

57.4 Memory map and register definition

The memory map for the VIU3 module is given below. The total address for each register is the sum of the base address for the VIU3 module and the address offset for each register. Also, please note that the bit order for each register bit field is [highest:lowest], whereas the overall register bits are numbered [lowest:highest].

VIU3 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400C_9000	Status And Configuration Register (VIU3_SCR)	32	R/W	0280_0000h	57.4.1/3264
400C_9004	Luminance Coefficients For Red, Green And Blue Matrix (VIU3_LUMA_COMP)	32	R/W	9512_A254h	57.4.2/3267
400C_9008	Chroma Coefficients For Red Matrix (VIU3_CHROMA_RED)	32	R/W	0331_0000h	57.4.3/3268
400C_900C	Chroma Coefficients For Green Matrix (VIU3_CHROMA_GREEN)	32	R/W	0660_0F38h	57.4.4/3269
400C_9010	Chroma Coefficients For Blue Matrix (VIU3_CHROMA_BLUE)	32	R/W	0000_0409h	57.4.5/3269

VIU3_SCR field descriptions

Field	Description
31 MODE32BIT	Select 32-bit or 16-bit output from the output formatter (block 6 in) **NOTE:** For RGB666 parallel input, when MODE32BIT is cleared, the output is {R[5:1], G[5:0], B[5:1]}; when MODE32BIT is set, the output is {R[5:0], 2'b00, G[5:0], 2'b00, B[5:0], 2'b00} 0 16-bit RGB or YUV 4:2:2 output 1 32-bit RGB or YUV 4:4:4 output. DITHER_ON and ROUND_ON are ignored if output is 32-bit RGB.
30 ROUND_ON	Round is on. Used when video data is stored in buffer as RGB565 format.
29 DITHER_ON	Dithering is on. Used when video data is stored in buffer as RGB565 format and ROUND_ON is not set.
28 FIELD_NO	Field number, extracted from ITU-656 stream.
27 DMA_ACT	DMA transfer of current field/frame is busy (write by software, cleared at end of transfer). When DMA_ACT is cleared, input video data is ignored and not put into FIFO.
26 SCALER_EN	Down scaling enable.
25 YUV2RGB_EN	YUV to RGB conversion enable.
24 BC_EN	Bright/Contrast adjust enable.
23 MODE444	YUV 4:4:4 mode enable bit. When it is set ITU decoder sends out YUV 4:4:4 format data, otherwise YUV 4:2:2 is sent by default. Down scaler works on YUV 4:2:2 format. So this bit shall be cleared when scaling is enabled.
22 RESERVED	This field is reserved.

Table continues on the next page...

VIU3_SCR field descriptions (continued)

Field	Description
21 ERROR_IRQ	Interrupt status bit. Write '1' to clear ERROR_IRQ.
20 DMA_END_IRQ	Interrupt status bit. Write '1' to clear DMA_END_IRQ.
19 VSTART_IRQ	Interrupt status bit. Write '1' to clear VSTART_IRQ.
18 HSYNC_IRQ	Interrupt status bit. Write '1' to clear HSYNC_IRQ.
17 VSYNC_IRQ	Interrupt status bit. Write '1' to clear VSYNC_IRQ.
16 FIELD_IRQ	Interrupt status bit. Write '1' to clear FIELD_IRQ.
15 RESERVED	This field is reserved.
14 ECC_EN	When this bit is set ECC errors generate ERROR_IRQ and the nature of ECC error gets reflected on the ERROR_CODE bit field.
13 ERROR_EN	Interrupt enable bit for ERROR_IRQ.
12 DMA_END_EN	Interrupt enable bit for DMA_END_IRQ.
11 VSTART_EN	Interrupt enable bit for VSTART_IRQ.
10 HSYNC_EN	Interrupt enable bit for HSYNC_IRQ.
9 VSYNC_EN	Interrupt enable bit for VSYNC_IRQ.
8 FIELD_EN	Interrupt enable bit for FIELD_IRQ.
7–4 ERROR_CODE	Error code. Signals errors that triggered error IRQ. Other values not given are reserved. 0000 No error 0001 DMA arm command given during vertical active, DMA_ACT does not accept the value on IPS bus. 0010 DMA arm command given during vertical blanking when DMA_ACT is set. 0100 Line too long 0101 Too many lines in a field/frame 0110 Line too short 0111 Not enough lines in a field/frame 1000 FIFO overflow 1001 FIFO underflow 1010 One bit ECC error 1011 Two or more bits ECC error
3–1 FORMAT_CTRL	Output pixel data format control. See below or refer to for detailed definition. Here 32-bit means MODE32BIT is set and 16-bit means MODE32BIT is cleared. RGB mode means YUV2RGB_EN is set and YUV mode means YUV2RGB_EN is cleared. C means U or V. Dummy means "don't care" data. 16-bit RGB mode: 3'b000: {R[7:3], G[7:2], B[7:3]};

Table continues on the next page...

VIU3_SCR field descriptions (continued)

Field	Description
	3'b001: {G[4:2], B[7:2], R[7:3], G[7:5]}; 32-bit RGB mode: 3'b000: {alpha, R, G, B}; 3'b001: {alpha, B, G, R}; 3'b010: {R, G, B, alpha}; 3'b011: {B, G, R, alpha}; 16-bit YUV mode: 3'b000: {C,Y}; 3'b001: {Y,C}; 32-bit YUV mode: 3'b000: {dummy, Y, U, V}; 3'b001: {dummy, Y, V, U}; 3'b010: {dummy, U, V, Y}; 3'b011: {dummy, V, U, Y}; 3'b100: {Y, U, V, dummy}; 3'b101: {Y, V, U, dummy}; 3'b110: {U, V, Y, dummy}; 3'b111: {V, U, Y, dummy};
0 SOFT_RESET	Writing 1 to this bit generates an internal reset to all components except registers in the VIU3 block. This bit should be set by software when an error interrupt is detected, and it needs to be cleared by software to release the software reset.

57.4.2 Luminance Coefficients For Red, Green And Blue Matrix (VIU3_LUMA_COMP)

The RGB pixel value is computed using following formulae:

$$\text{Red} = \frac{(Y-16)\cdot \text{Y-RED}}{512} + \frac{(Cr-128)\ \text{CR\_RED}}{512} + \frac{(Cb-128)\ \text{CB\_RED}}{512}$$

$$\text{Green} = \frac{(Y-16)\cdot \text{Y\_GREEN}}{512} + \frac{(Cr-128)\ \text{CR\_GREEN}}{512} + \frac{(Cb-128)\ \text{CB\_GREEN}}{512}$$

$$\text{Blue} = \frac{(Y-16)\cdot \text{Y\_BLUE}}{512} + \frac{(Cr-128)\ \text{CR\_BLUE}}{512} + \frac{(Cb-128)\ \text{CB\_BLUE}}{512}$$

The multiplications with Y_red, Y_green, and Y_blue are unsigned multiplications. The multiplications with Cr_red, Cb_red, Cr_green, Cb_green, Cr_blue, and Cb_blue are signed multiplications. The addition is saturated to prevent overflow.

VIU3_INVSZ field descriptions

Field	Description
31–16 LINEC	(LINEC[15:0]) Expected number of active lines in each input video field/frame. It shall only be configured when DMA is non-active, during vertical blanking If more lines are found during data receive part, a "too many lines" error interrupt is generated when ERROR_IRQ is set. Redundant lines are discarded. If fewer lines are found during data receive part, a "not enough lines error interrupt is generated when ERROR_IRQ is set.
15–0 PIXELC	(PIXELC[15:0]) Expected number of active pixels in each input video line, it shall be an integer multiple of 4. It shall only be configured when DMA is non-active, during vertical blanking. If more pixels are found during data receive part, a "line too long" error interrupt is generated when ERROR_IRQ isset. Redundant pixels are discarded. If less pixels are found during data receive part, a line too short error interrupt is generated when ERROR_IRQ is set.

57.4.9 High IPM Request Priority Alarm (VIU3_HPRALRM)

Address: 400C_9000h base + 20h offset = 400C_9020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VIU3_EXT_CONFIG field descriptions

Field	Description
31–13 RESERVED	This field is reserved.
12 CS_EN	Chroma swap enable bit. It's used to control how combining Y and C when output format is YUV422 mode. By default, for YUV422 mode(for example, assume 4 pixels per line here), the data in memory is Y0U0, Y1V0, Y2U2, Y3V2. When CS_EN is set, it becomes Y0V0, Y1U0, Y2V2, Y3U2. An application senario of CS_EN is that when mirror is on, the data will be Y3V2, Y2U2, Y1V0, Y0U0 by default. The first chrmo is V, instead of U. If CS_EN is set, the output data become Y3U2, Y2V2, Y1U0, Y0V0. 0 Chroma swap is disabled. 1 Chroma swap is enabled.
11 LENDIAN	Data endian control bit. This bit controls the endian of the IPM data bus. 0 Big endian 1 Little endian
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 RGB2YUV_EN	RGB to YUV conversion enable
8 DE_VALID	External data enable indicator is valid at parallel input modes. 0 DE is invalid 1 DE is valid
7–5 INP_FORMAT	Input video format select bits. It should be set correctly according to the video input. 000 10/8bit ITU stream 001 24bit parallel YUV. Normally it is YUV444 010 Reserved

Table continues on the next page...

VIU3_EXT_CONFIG field descriptions (continued)

Field	Description
	011 Reserved 100 24bit parallel RGB. It is RGB888 101 8bit serial RGB. It is RGB888 110 18bit parallel RGB. It is RGB666 111 16bit parallel RGB. It is RGB565
4 PCLK_POL	Pixel clock polarity control bit. pix_clk will be reversed when the bit is set. 0 Active high 1 Active low
3 VSYNC_POL	Vsync polarity control bit. Vsync will be reversed when the bit is set. 0 Active high 1 Active low
2 HSYNC_POL	Hsync polarity control bit. Hsync will be reversed when the bit is set. 0 Active high 1 Active low
1 DE_POL	Data enable polarity control bit. DE will be reversed when the bit is set. 0 Active high 1 Active low
0 HMIRROR_EN	Horizontal mirror enable.

57.4.17 Red, Green and Blue Coefficients for Luminance component (VIU3_RGB_Y)

The YUV pixel value is computed using the following formulae:

$$Y = \frac{RY \cdot R}{512} + \frac{GY \cdot G}{512} + \frac{BY \cdot B}{512} + 16$$

$$U = \left(-\frac{RU \cdot R}{512}\right) + \left(-\frac{GU \cdot G}{512}\right) + \frac{BU \cdot B}{512} + 128$$

$$V = \frac{RV \cdot R}{512} - \frac{GV \cdot G}{512} - \frac{BV \cdot B}{512} + 128$$

All cofficients are unsigned.

Address: 400C_9000h base + 40h offset = 400C_9040h

57.5 Functional Description

The VIU3 accepts parallel RGB, serial RGB, parallel YUV and ITU-R BT.656 compatible video streams on its parallel interface, decodes it and optionally performs processes like scaling, brightness and contrast adjust, RGBYUV to YUVRGB conversion, and de-interlace (weaving), then stores the result video stream to the system memory which can then be displayed by a display controller, or post processed.

Functions of the VIU3 are designed in a way that they can be flexibly enabled or disabled by software. But there are a few limitations as listed below:

- The down scaler works on YUV 4:2:2 format or RGB888 formats, so to enable the scalar, decoder shall be configured in YUV 4:2:2 or RGB888 mode.
- To use the scaler, progressive video input shall be used for display quality's sake, and the de-interlace shall be disabled.

57.5.1 Input Formats

VIU3 accepts parallel RGB, serial RGB, parallel YUV and ITU-R BT.656 compatible video streams on its parallel interface. Below is the description for the timing of input video formats.

57.5.1.1 ITU656

The ITU-R BT.656-4 recommendation describes the means of interconnecting digital television equipment operating on the 525-line or 625-line standards and combines with the 4:2:2 encoding parameters as defined in the ITU-R BT.601 recommendation.

The data stream structure on ITU-R BT.656-4 interface is shown in the following figure. There are two timing reference signals, one at the beginning of each video data block (start of active video, SAV) and one at the end of each video data block (end of active video, EAV).

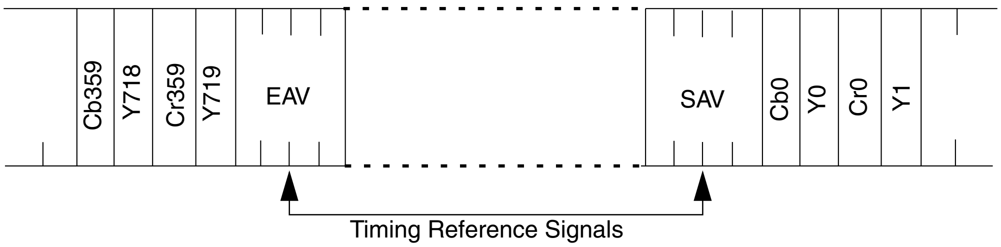

Figure 57-21. Interface Data Stream of ITU-R BT.656-4

Each timing reference signal consists of a four-word sequence in the following format: FF 00 00 XY. Values are expressed in hexadecimal notation. Value FF and 00 are reserved to be used in the timing reference signals.

The first three words are a fixed preamble. The fourth word contains information defining field 2 identification, the state of field blanking, and the state of line blanking. The assignment of bits within the timing reference signal is shown in the table below.

Table 57-22. Video Timing Reference Codes

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9(MSB)	1	0	0	1
8	1	0	0	F(0: field 1, 1: field 2)
7	1	0	0	V(0: elsewhere, 1: field blanking)
6	1	0	0	H(0: in SAV, 1: in EAV)

Table continues on the next page...

Table 57-22. Video Timing Reference Codes (continued)

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

In above table, bits P0, P1, P2, P3 have states dependent on the states of the bits F, V and H. At the receiver side this arrangement permits one-bit errors to be corrected and two-bit errors to be detected.

Progressive video is also composed of fields; but instead of containing even lines in one field and odd lines in the other, the fields contain contiguous lines, i.e., field0 contains lines 1,2,3,... and field1 contains rest of the lines starting from (last line number of field0 + 1). And the F bit cannot be ignored in case of progressive frame.

Refer to the ITU-R BT.656-4 recommendation for more details.

57.5.1.2 Parallel Input Format

VIU3 also accepts parallel input video formats. It includes 24bit RGB888, YUV444, 18bit RGB666 and 16bit RGB565 formats. Their data streams are similar. The following caveats apply to the timing diagram below:

- FID must change state 3 Hsync pulses into Vsync.
- The first -//- break represents at least 10 lines.
- A field should contain more than 16 active lines.
- Hsync pulse should be longer than 60 pixel clock cycles.
- A active line should contain more than 24 pixels.

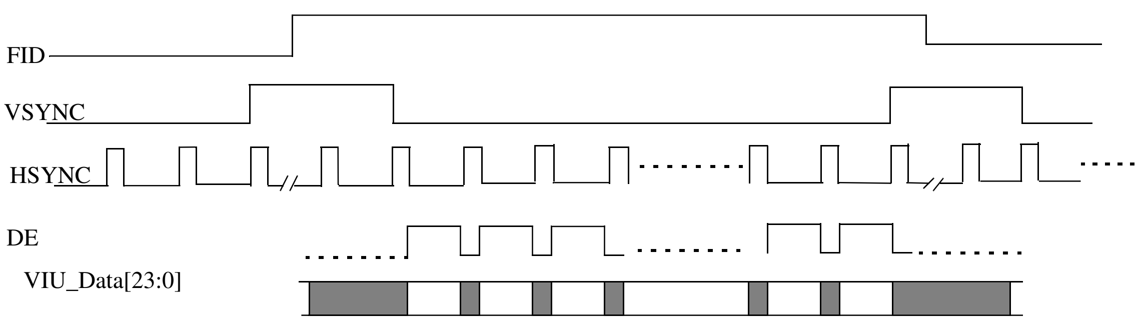

Figure 57-22. Parallel Input Timing

57.5.1.3 Parallel YC Format

Parallel YC video should be in YUV222 format. The timing diagram is provided below.

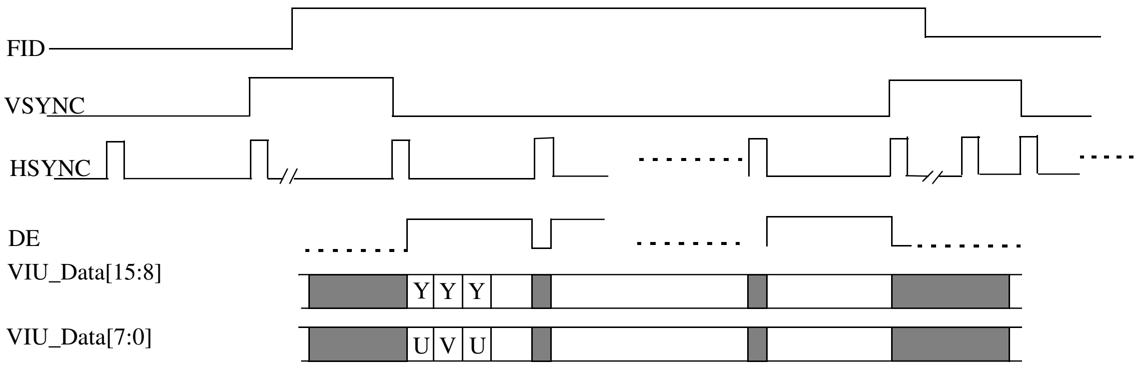

Figure 57-23. Parallel YC Timing

57.5.1.4 Serial RGB888 Format

The timing diagram of serial RGB888 is shown below.

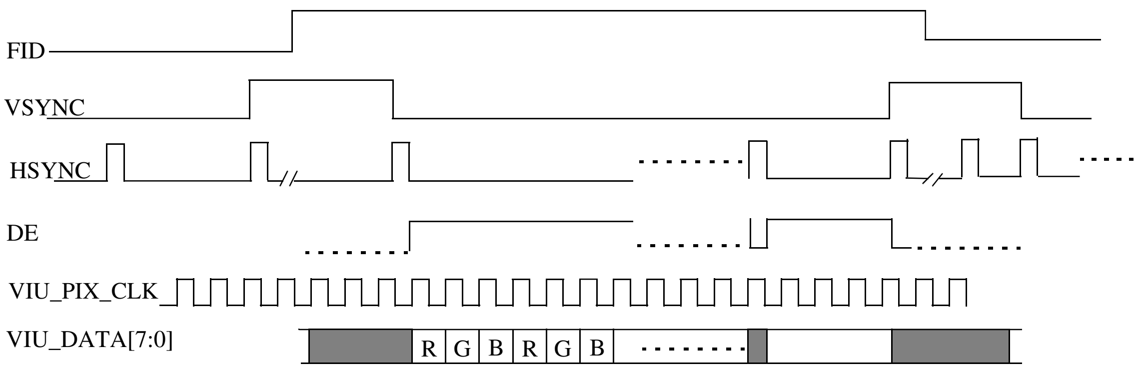

Figure 57-24. Serial RGB888 Timing

57.5.2 Input Synchronizer

The Synchronizer block (1) captures ITU656 protocol signals from the interface, and synchronizes them to the IPG_CLK domain.

57.5.3 Decoder

The ITU Decoder block (2) detects the ITU656 timing reference signal (consists of a four-word sequence in the following format: FF-00-00-XY) and extracts HSYNC, VSYNC, field number signals and video data from the ITU data stream. The format of active pixel data from the ITU stream is YUV 4:2:2. The decoder block can directly send out this YUV 4:2:2 data, or interpolate it to YUV 4:4:4 format and send it out. This is determined by the MODE444 field in the SCR register. This bit shall be set if the down-scaler is enabled, because the down-scaler works on YUV 4:4:4 data format.

57.5.4 Scaling

VIU3 supports up to 1/8 horizontal and vertical down-scaling, as well as 2x horizontal up-scaling.

57.5.4.1 Down Scaling

The Down-scaler block (3) performs down-scaling to the incoming video stream. It is able to scale down the input video stream by a fractional scaling ratio up to 1/8. The down-scaler block can be enabled/disabled by software via the SCALER_EN bit in the SCR register. To use the down-scaler video data extracted from ITU decoder shall be in YUV 4:4:4 format.

The down-scaler uses a bi-linear filter with simple linear interpolation between the two nearest neighbors, on both horizontal and vertical direction. Scaling is firstly done on the horizontal direction (called XScale), and then the vertical direction (called YScale). Different scaling factors are supported on horizontal direction and vertical direction.

Assuming the scaling factors are (factor_h, factor_v), in theory for every pixel (x, y) of the scaled picture the coordinates of the corresponding pixel in the incoming picture (x1, y1) can be calculated by multiplying the coordinates with the scaling factors, say (x1 = x * factor_h, y1 = y * factor_v). Now because the scaling factors can be fractions, the coordinates (x1, y1) are not integer anymore, they are fractional values. The scalers use the integer part of (x1, y1) to find the two neighboring pixels from the incoming picture as input to the filters, and the fractional part to derive the weighting factors for interpolation.

The scaling factors, (factor_h, factor_v), are both 11 bit with the lower 8 bit as the factional part and the highest 3 bit the integer part. It is capable of scaling the input picture by up to 8, in steps of 1/256. It is by 8 if the factor is programmed as all zeros.

Instead of using multipliers to calculate (x1, y1), two 20-bit phase accumulator is used to step through the source pixels/or lines, where the lower 8 bit is the fractional part. For every output pixel/or line the phase adder is added to the accumulator. With the 12 bit integer part of the accumulator, up to 4096 source pixels/or lines can be supported.

So for each target pixel, the current accumulator position is used to determine how the pixel is going to be produced. As an example, accumulator value 0x123.3a means the step position is between pixel[0x123] and pixel[0x124], and the output pixel will be calculated by (pixel[0x124] * (0x100 - 0x3a) + pixel[0x123] * 0x3a) >> 8. The same concept is used for horizontal and vertical scaling.

Because of the vertical scaling, a line buffer is used for each color component to store the data from horizontal scaling, it stores one line of data. Size of the line buffer determines the maximum video output size after scaling.

The scaling factors are programmed via the HFACTOR and VFACTOR registers. Video size after scaling is programmed via the VID_SIZE register.

Three scalers are instantiated in the down-scaler block, one for each component.

57.5.4.2 Up-scaling

The theory of up-scaling is the same with down-scaling. When HFACTOR is smaller than 1, up-scaling is implemented by VIU3 scaler. But note that VIU3 does not support vertical up-scaling, and HFACTOR should not be less than 0.5.

Note

The scaled pixel count per line shall be an integer multiple of 2 in 32-bit output mode, or 4 in 16-bit output mode. The user shall divide the input pixel count by the horizontal scaling factor and truncate the result to a multiple of 2 or 4.

Note

To achieve good display quality, progressive video input shall be used if down-scaling is needed.

57.5.5 Brightness and Contrast Adjust

The B/C Adjust block (4) performs brightness and contrast adjustment on the input video stream via three internal look-up-tables, one table per color component. Each table contains 256 8-bit entries, it maps every incoming pixel to the value of one of its entries

according to the original value of the pixel. This feature allows the user to adjust brightness and/or contrast of the incoming picture according to three arbitrary adjustment curves, one adjustment curve per color component.

To use this feature, the B/C adjust look-up-table shall be programmed in software in the following format.

Table 57-23. B/C Adjust Look-up-table Format

Color Component	BC LUT Offset	Local Address [1:0]			
		00	01	10	11
Y	0x000	$BC0_Y$	$BC1_Y$	$BC2_Y$	$BC3_Y$
	......				
	0x0FC	$BC252_Y$	$BC253_Y$	$BC254_Y$	$BC255_Y$
U	0x100	$BC0_U$	$BC1_U$	$BC2_U$	$BC3_U$
	......				
	0x1FC	$BC252_U$	$BC253_U$	$BC254_U$	$BC255_U$
V	0x200	$BC0_V$	$BC1_V$	$BC2_V$	$BC3_V$
	......				
	0x2FC	$BC252_V$	$BC253_V$	$BC254_V$	$BC255_V$

Two registers are provided to program the look-up-table, they are LUT_ADDR and LUT_DATA. LUT_ADDR is the current address pointer, which always points to the current table offset to be programmed. It can be set by software, and it increases (by 4) automatically when each word is written to the table, and it falls back to 0x000 if the current value is 0x2FC and the last word is written to the table. LUT_DATA is the table data entry, data written to this register will be stored into the table, to the address pointed to by LUT_ADDR. This register shall only be written by 4-byte word. With the combination of these two registers the user can program the B/C look-up-table conveniently, either program the whole table, or reprogram the table for one color component only, or even change one single arbitrary word in the table.

The B/C adjust can be enabled/disabled by software via the BC_EN bit in the SCR register.

57.5.6 YUV to RGB Conversion

The YUV2RGB block (5) is used to convert YUV (4:2:2 or 4:4:4) to RGB (888 or 565). The coefficients of the YUV to RGB conversion matrix are programmed via four registers. When the input is YUV 4:2:2, it is interpolated to YUV 4:4:4 first.

57.5.7 Round and Dither

In RGB565 output mode, when pixel data is converted from RGB888 to RGB565 the image is anamorphic more or less, because of losing color information conveyed by the least significant two or three bits of the original color components, which are dropped. VIU3 block provides two simple algorithms, round and dither, to compensate this color information loss.

57.5.7.1 Round

In round mode, VIU3 will round to 1 in LSB if the decimal fraction is bigger than 0.5 and ignore the smaller fraction when ROUND_ON is set in the SCR register.

57.5.7.2 Dither

Dither is a little more complex but better than round for recovering image. It is a statistical compensation algorithm. It does not render all pixels with the same grey or color level, but some with the lower one, and some with a color level of 1 LSB more. The selection of adding one LSB or not depends on the position of the pixel on the screen.

The figure below shows the implementation of dither in the VIU3 block.

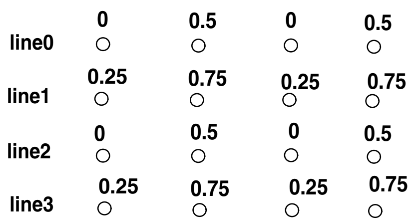

Figure 57-25. Dither Implementation

The number above the pixel position in the diagram is the compensation value for this pixel. When pixels have a value of 0.25, they are rendered 0 in 75% of the pixels and 1 in 25% of pixels. This averages to 0.25. Similarly, pixel values of 0.5, 0.75, and 1.0 are rendered 50%, 75% and 100% of the pixels as 1. For human eyes, this rendering result of dither makes the holistic image smoother and closer to the original one.

57.5.8 Output Formatter

The Output Formatter block (6) accepts YUV or RGB data from the YUV2RGB block, arranges them in expected format, and then sends it to the DMA engine. The FORMAT_CTRL field in SCR register controls how the VIU3 stores data to system memory; see the following figure for details.>

Table 57-24. VIU3 Output Data Stream Format

Pixel Format	FORMAT _CTRL[1]	Local Address [2:0]							
		000	001	010	011	100	101	110	111
RGB 565	000	R0[7:3], G0[7:2], B0[7:3]		R1[7:3], G1[7:2], B1[7:3]		R2[7:3], G2[7:2], B2[7:3]		R3[7:3], G3[7:2], B3[7:3]	
	001[2]	G0[4:2], B0[7:3], R0[7:3], G0[7:5]		G1[4:2], B1[7:3], R1[7:3], G1[7:5]		G2[4:2], B2[7:3], R2[7:3], G2[7:5]		G3[4:2], B3[7:3], R3[7:3], G3[7:5]	
RGB 8888	000	A0	R0	G0	B0	A1	R1	G1	B1
	001	A0	B0	G0	R0	A1	B1	G1	R1
	010	R0	G0	B0	A0	R1	G1	B1	A1
	011	B0	G0	R0	A0	B1	G1	R1	A1
YUV 4:2:2	000	U0	Y0	V0	Y1	U2	Y2	V2	Y3
	001	Y0	U0	Y1	V0	Y2	U2	Y3	V2
YUV 4:4:4	000	dummy	Y0	U0	V0	dummy	Y1	U1	V1
	001	dummy	Y0	V0	U0	dummy	Y1	V1	U1
	010	dummy	U0	V0	Y0	dummy	U1	V1	Y1
	011	dummy	V0	U0	Y0	dummy	V1	U1	Y1
	100	Y0	U0	V0	dummy	Y1	U1	V1	dummy
	101	Y0	V0	U0	dummy	Y1	V1	U1	dummy
	110	U0	V0	Y0	dummy	U1	V1	Y1	dummy
	111	V0	U0	Y0	dummy	V1	U1	Y1	dummy

1. All values not shown in the table shall be considered as reserved and shall not be used.
2. This format is basically intended for data communication with any little-endian peripheral in the system, assuming big-endian system memory is used.

NOTE

RGB666 input can be stored in memory in RGB565 or RGB8888 formats. When stored as RGB565, the R[0] and B[0] component of RGB666 input will be discarded. When stored as RGB8888, the RGB666 input data will be reflected in memory as {R[5:0], 2'b00, G[5:0], 2'b00, B[5:0], 2'b00}. The position of Alpha bit will depend on the FORMAT_CTRL setting.

57.5.9 High Priority Alarm

FIFO_FILL is a status field which indicates the amount of data in the FIFO. The HI_PRIO_ALARM register is a threshold such that, when the data number in the FIFO is larger than HI_PRIO_ALARM, the DMA request will be high-priority on the AMBA crossbar side. The purpose of this register is to enhance DMA performance. Normally the reset value should be sufficient; however, if the FIFO is seen to overflow, the user should lower the threshold in order to allow the DMA to service the FIFO more frequently.

57.5.10 DMA and De-interlace

The DMA engine block (7) functions as the FIFO controller and DMA engine. It stores the data from the output formatter block into a FIFO and then writes them to system memory via the IPM interface.

VIU3 block has an embedded DMA. When video data is converted to RGB format and placed into a 256 × 64 bit FIFO, it waits to be transferred to memory by the internal DMA.

After doing some necessary register configuration, such as coefficients, INVSZ and DMA_ADDR, user can activate DMA by setting the DMA_ACT of the status and configuration register. But note that DMA_ACT can be configured only during vertical blanking since the VIU3 block will not transfer a fragment of video field to memory. If it is configured during field active time, DMA transfer cannot be started and an error interrupt will be asserted.

The VIU3 block asserts a transfer request when there is enough data in the FIFO for one transfer. Normally one transfer conveys 32 bytes from FIFO to memory. At the end of a line, all remaining data is transferred, though it may not be as much as 32 bytes.

VIU3 also provides a simple way to de-interlace for interlaced or pseudo-interlaced video images. It is implemented by setting the DMA_ADDR and DMA_INC registers.

The figure below shows the implementation of de-interlace. The value of DMA_INC is added to the rounded address at the end of every active line. So, when DMA_INC is zero, pixel data is stored in memory line by line, meaning de-interlace is off, as shown in figure (1) and (2); otherwise, when DMA_INC equals to one-line memory mapped pixel size and DMA_ADDR(2) = DMA_ADDR(1) + DMA_INC, the odd field and even field will be merged into one frame in memory, as shown in figure (3).

Here DMA_ADDR(1) means base address of field 1, and DMA_ADDR(2) means base address of field 2. Memory mapped line size means memory size that is occupied by one active line pixels. It depends on pixel number of one line and video data format (RGB888 or RGB565). See the register description section for more details.

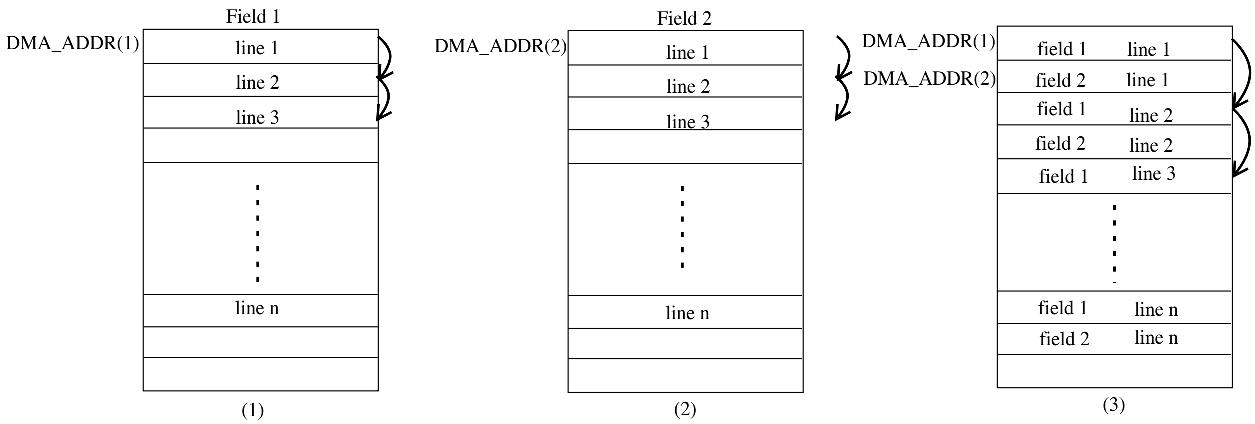

Figure 57-26. Implementation of De-interlace

When the HMIRROR_EN bit is set in the EXT_CONFIG register, the image can be mirrored in the horizontal direction, as illustrated below.

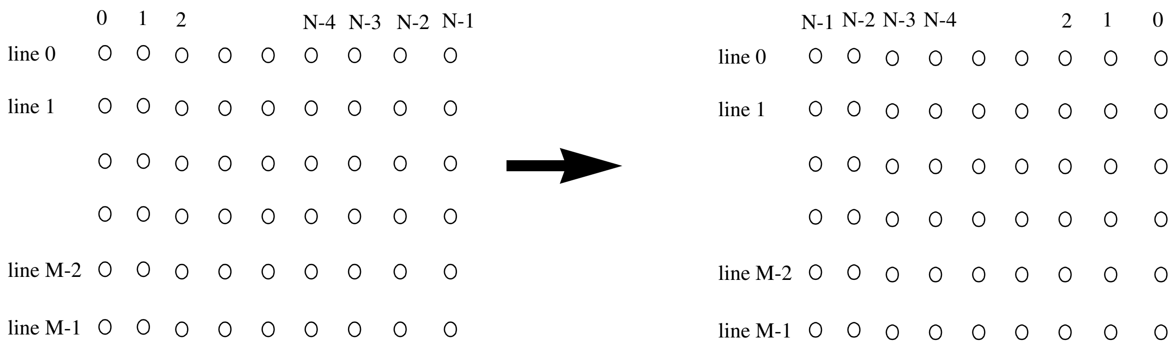

Figure 57-27. Horizontal Image Mirror

57.5.11 Error Case

Normally, the user should provide a standard and totally ITU-compatible video stream to the VIU3 block. However, it is difficult to avoid unexpected errors all the time. VIU3 can manage error cases like ECC error, line too long, line too short, too many lines, not enough lines in a field, and FIFO overflow.

- ECC error: ITU stream provides 4-bit error correcting code P[3:0] in its SAV and EAV. It is decoded in VIU3 to use the correct field number, horizontal sync and vertical sync bits. It can correct one bit errors and find two bit errors. When an ECC error is found, an interrupt is asserted.
- Line too long error: When pixels of active line is longer than PIXELC, a line too long error interrupt is asserted and redundant pixels are discarded.

- Too many lines error: When active lines of a field are bigger than LINEC, a too many lines error interrupt is asserted and redundant lines are discarded.
- Line too short error: When pixels of active line is less than PIXELC, a line too short error interrupt is asserted.
- Not enough line error: When active lines of a field is less than LINEC, a not enough line error interrupt is asserted.
- FIFO overflow error: If the system bus is blocked for a long time, video data is stored in FIFO and causes FIFO overflow. When FIFO overflow occurs, an interrupt is asserted and incoming data is discarded until FIFO works normally again. Current field is jumbled. However, VIU3 recovers to work at the next field if the bus is unblocked at that time.
- FIFO underflow: When the FIFO is read when it is empty, a FIFO underflow error interrupt is asserted. Normally, this error should not occur.

VIU3 can manage the above error cases to a certain extent. However, when it does not recover to a working state the user should write the SOFT_RESET bit of the status and configuration register to reset the VIU3 block.

57.6 Initialization/Application Information

Initialization steps and startup information are given below.

57.6.1 Initialization Information

When the VIU3 block comes out of reset, software should implement the following steps to start this block.

1. Program the SCR register to set the VIU3 to the desired operation mode
   - To enable YUV 4:2:2 to 4:4:4 interpolation in the ITU decoder, set the MODE444 bit[2]
   - To enable the down-scaler, set the SCALER_EN bit
   - To enable B/C adjust, set the BC_EN bit

2. MODE444 bit shall not be set when the down-scaler is enabled.

- To enable RGB565 output mode, set the YUV2RGB_EN bit and clear the MODE32BIT bit. Optionally set the DITHER_ON bit or the ROUND_ON bit to enable dither or round[3]
- To enable RGB8888 output mode, set the YUV2RGB_EN and MODE32BIT bits
- To enable YUV output mode, clear the YUV2RGB_EN bit

2. Set the FORMAT_CTRL field so that the VIU3 outputs data in the correct format. Configure the input video size via the INVSZ register.
3. If it is desired to use RGB output, configure YUV to RGB conversion coefficients or use the default values after reset.
4. If it is desired to use the down scaling function, program the down scaling factors and destination video size after scaling.
5. If it is desired to use the B/C adjust function, program the B/C adjust look-up-table via the LUT_DATA and LUT_ADDR registers.
6. Configure the HPRALRM and ALPHA registers if necessary.
7. Set the VSYNC_EN and/or FIELD_EN bits in the SCR register to enable vsync or field interrupt. Meanwhile, disable error interrupt.
8. When software receives a vsync interrupt and/or field interrupt, read FIELD_NO bit of the SCR register[4].
9. According to the FIELD_NO bit, program the DMA_ADDR register. This is the field start address in system memory, or frame start address in progressive video input mode.
10. If it is desired to use the de-interlace (weaving) function, program the line start address offset value in the DMA_INC register[5].
11. Clear error status first if necessary.
12. Write the DMA_ACT bit of the SCR register to start FIFO and DMA transfer. This operation actually starts the VIU3 to operate.

3. If DITHER_ON or ROUND_ON are both set, only round will be enabled.
4. Reading the FIELD_NO bit is optional, especially in progressive video input mode.
5. Progressive video input shall be used when down scaling is enabled for better display quality.

57.6.2 Application Information

Normally, the user shall not change the register values of the function enable bits, input/output video size, color conversion coefficients, DMA_INC, MODE32BIT, scaling factors and B/C adjust look-up-table contents after VIU3 is started up. When the video input source is changed, the user should reset the VIU3 and re-configure the related registers.

57.6.2.1 Register Configuration Timing Window

As mentioned above, dynamic configuration of registers is not recommended because it may cause error if it is not configured in a certain timing window, especially for INVSZ and DMA_INC.

Register configuration timing window is shown in the below diagram. All registers, except for the SOFT_RESET bit, are recommended to be configured during vertical blanking, after DMA transfer is done and the field identification bit is changed (field interrupt is asserted).

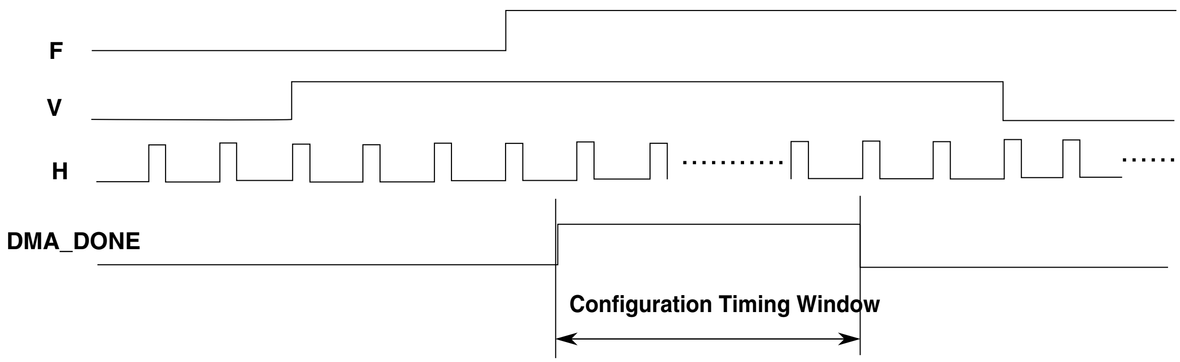

Figure 57-28. Register Configuration Timing Window

Chapter 58
Timing Controller TCON

58.1 Introduction

The Timing Controller module (TCON) provides an alternative interface for the DCU3 that provides RGB data and timing signals for "raw" TFT panels which have no embedded TCON.

58.1.1 Features

- Flexible timing generation unit supporting 12 timing signal channels
- Support bit mapping of 8-bit or 6-bit color depth
- Blanking of RGB data during inactive period (driven to all "0" or all "1")

58.1.2 Modes of Operation

The TCON has 2 operation modes:

- Bypass mode: the input signals are passed through, and the TCON is turned off
- TTL mode: the TCON is functional, driving parallel RGB output, and the TCON timing signals

58.2 External Signal Descriptions

The TCON has the following external signals:

Table 58-1. TCON External Signals

Signal	Description	I/O	Reset
data_out[25:0]	pixel data and clock out	O	0
tcon_out[11:0]	12 tcon timing signals	O	0

58.3 Memory map and register definition

The memory map for the TCON module is given below. The total address for each register is the sum of the base address for the TCON module and the address offset for each register.

TCON memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4003_D000	TCON control1 register (TCON0_CTRL1)	32	R/W	0000_000Ch	58.3.1/3299
4003_D004	Bit map control register (TCON0_BMC)	32	R/W	0000_0000h	58.3.2/3301
4003_D008	Comparator 0 configure register (TCON0_COMP0)	32	R/W	0000_0FFFh	58.3.3/3302
4003_D00C	Comparator 1 configure register (TCON0_COMP1)	32	R/W	0000_0FFFh	58.3.4/3303
4003_D010	Comparator 2 configure register (TCON0_COMP2)	32	R/W	0000_0FFFh	58.3.5/3304
4003_D014	Comparator 3 configure register (TCON0_COMP3)	32	R/W	0000_0FFFh	58.3.6/3305
4003_D018	Comparator 0 compare value mask register (TCON0_COMP0_MSK)	32	R/W	0000_0FFFh	58.3.7/3305
4003_D01C	Comparator 1 compare value mask register (TCON0_COMP1_MSK)	32	R/W	0000_0FFFh	58.3.8/3306
4003_D020	Comparator 2 compare value mask register (TCON0_COMP2_MSK)	32	R/W	0000_0FFFh	58.3.9/3306

58.3.1 TCON control1 register (TCONx_CTRL1)

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	TCON_EN	Reserved	TCON_BYPASS	INV_EN	TCONx_INV											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	INIT_DELAY			V_REF_SEL			H_REF_SEL		VLEN		HSYNC_INV	VSYNC_INV	COLOR_DEPTH	RGB_PADDING_EN	RGB_PADDING	Reserved
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0

TCONx_CTRL1 field descriptions

Field	Description
31 TCON_EN	**NOTE:** Program the TCON_CTRL1 register to configure the operation mode of TCON and enable TCON (It is recommended to do this in two steps, and set TCON_EN in the second). 0 Disable TCON. 1 enable TCON.
30 RESERVED	This field is reserved.
29 TCON_BYPASS	Controls whether TCON is bypassed. 0 Not bypass TCON. State of the TCON is decided by TCON_EN. 1 Bypass TCON, both data and timing signals will pass through the TCON unmodified. see the "Bypass Mode" section for pin mapping in that mode.
28 INV_EN	The input pixel (n) is compared with pixel (n-1). If more than half of the RGB data bits toggle, the pixel (n) output will be inverted and the tcon_out[11] flags this data inversion to the gray scale reference. tcon_out[11] =1 -> data_out is inverted, tcou_out[11] =0 -> data_out is not inverted. Intention of this feature is for board level EMI reduction. 0 Disable output data inversion 1 Enable output data inversion

Table continues on the next page...

TCONx_CTRL1 field descriptions (continued)

Field	Description
27–16 TCONx_INV	TCONx output inversion control 0 do not invert tconx 1 invert output tconx
15–13 INIT_DELAY	(INIT_DELAY[2:0]) Initialization delay, set the number of frames before the TCON starts to output timing signals.
12–10 V_REF_SEL	(V_REF_SEL[2:0]) v_ref selector, please refer to the "Toggle generator" section for use of v_ref signal. Note: pulse generated must be vertical based for the toggle generator. 000 select tcon_pulse0 output as v_ref 001 select tcon_pulse1 output as v_ref 010 select tcon_pulse2 output as v_ref 011 select tcon_pulse3 output as v_ref 100 select tcon_pulse4 output as v_ref 101 select tcon_pulse5 output as v_ref 110 select tcon_pulse0 output as v_ref, while reset vtgl_counter and vtgl[3] to 0 at rising edge of v_ref. 111 select tcon_pulse0 output as v_ref, while set vtgl_counter to 1 and reset vtgl[3] to 0 at rising edge of v_ref.
9–8 H_REF_SEL	(H_REF_SEL[2:0]) h_ref selector, please refer to the "Toggle generator" section for use of h_ref signal. 00 select tcon_comp0 output as h_ref. 01 select tcon_comp1 output as h_ref. 10 select tcon_comp2 output as h_ref. 11 select tcon_comp3 output as h_ref.
7–6 VLEN	(VLEN[1:0]) Maximum counter value for vtgl_counter in the toggle generator. Please refer to to the "Toggle generator" section for detailed functionality of this field.
5 HSYNC_INV	Horizontal sync. 0 hsync_in signal is active high 1 hsync_in signal is active low
4 VSYNC_INV	Vertical sync. 0 vsync_in signal is active high 1 vsync_in signal is active low
3 COLOR_DEPTH	Color depth of each color component 0 6 bits, the 2 LSB's are set to 2'b0 1 8 bits
2 RGB_PADDING_EN	RGB data padding enable 0 disable padding during blanking 1 enable padding during blanking
1 RGB_PADDING	RGB data driven during blanking. 0 all "0" 1 all "1"
0 RESERVED	This field is reserved.

58.3.2 Bit map control register (TCONx_BMC)

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved

R W	COMPARATOR_SEL		Reserved		RESET											
Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

TCONx_PULSE0 field descriptions

Field	Description
31–30 FUNC_SEL	(FUNC_SEL[1:0]) Select the type of pulse, horizontal/vertical/or mix 00 SET/RESET value both for horizontal compare 01 SET/RESET value both for vertical compare, signal transition point determined by COMPARATOR_SEL

Table continues on the next page...

TCONx_PULSE0 field descriptions (continued)

Field	Description
	10 SET/RESET value both for vertical compare, signal transitions at the beginning of the line which is matched. 11 SET value for horizontal compare, RESET value for vertical compare. Signal transition point for RESET determined by COMPARATOR_SEL.
29–28 RESERVED	This field is reserved.
27–16 SET	(SET[11:0]) Set point compare value Note: There will be a two pixel clock cycle delay between the internal pixel counter and the output pixel data in horizontal direction, user should take this two cycle delay into account when programming this field. See the "Pulse generator" section for a detailed explanation.
15–14 COMPARATOR_SEL	(COMPARATOR_SEL[1:0) When FUNC_SEL is set to 01, 1 of the 4 comparator outputs is selected to define the horizontal change point for both SET/RESET. When FUNC_SEL is set to 11, 1 of the 4 comparator outputs is selected to define the horizontal change point for RESET. Note: when FUNC_SEL set to 01 or 11, user should program the corresponding comparator for horizontal compare to ensure the timing signal is generated as expected. 00 select comparator0 01 select comparator1 10 select comparator2 11 select comparator3
13–12 RESERVED	This field is reserved.
11–0 RESET	(RESET[11:0]) Reset point compare value Note: There will be a two pixel clock cycle's delay between the internal pixel count and the output pixel data in horizontal direction, user should take this two cycle delay into account when programming this field. See the "Pulse generator" section for a detailed explanation.

58.3.12 Pulse 1 configure register (TCONx_PULSE1)

Address: Base address + 2Ch offset

TCONx_CTRL2 field descriptions

Field	Description
31–25 RESERVED	This field is reserved.
24–16 CLK_OFFSET	(CLK_OFFSET[8:0]) Output pixel clock offset value in half ipg_clk cycle unit. please refer to the "Clock/ Data Skew Adjustment" section for use of this field. The valid range of this field is to 0 to 2N-1 in TTL mode, where N=(DIV_RATIO+1).
15–8 RESERVED	This field is reserved.
7–0 DIV_RATIO	(DIV_RATIO[7:0]) TCON pixel clock divide ratio. When DIV_RATIO set to N, pix_clk will be ipg_clk divided by N+1.

58.4 Functional Description

The major functions of the TCON are to generate timing signals needed to drive the external row drivers and column drivers, and map the RGB data bits to output pins. It accepts RGB data, Horizontal/Vertical synchronization signals from the Display Controller Unit module, maintains two internal counters (x_count, and y_count), and uses these to generate the timing signals. In order to support as many types of panels as possible, the timing generation unit has been designed to be flexible and can be configured freely to generate complicated timing signals. See Timing signal generator for details about the timing signal generation unit.

The TCON has two operation modes: TTL mode, and bypass mode. In bypass mode the input signals are passed through the TCON unchanged, and in TTL mode the TCON performs signal (the RGB data and pixel clock) bit mapping. For details of the operation modes see Modes of operation, and for the signal bit mapping see Bit Mapping Control (BMC).

58.4.1 Modes of operation

Various operation modes are discussed below.

58.4.1.1 TTL mode

In TTL mode the TCON drives the RGB data, pixel clock, and the TCON timing signals all via TTL interface. In this mode simple signal bit mapping is performed, see Bit mapping in TTL mode.

It is also possible to assign the pixel clock to any one of the 25 output pins in TTL mode, see Clock mapping in TTL mode.

To enable the TTL mode, the user shall set the TCON_CTRL1[TCON_BYPASS]='0', and TCON_CTRL1[TCON_EN]='1'.

58.4.1.2 Bypass mode

For applications where the TCON is not in use, a bypass mode is provided in which the input signals from the Display Control Unit are passed through the TCON unchanged. See the table below for how the input signals are assigned to the TCON output.

Table 58-164. input/output signal mapping in bypass mode

Input	Output
data_in[23:0]	data_out[25:2]
pix_clk	data_out[1]
dcu_tag	tcon_out[0]
hsync_in	tcon_out[1]
vsync_in	tcon_out[2]
data_en_in	tcon_out[3]

To put the TCON in bypass mode set TCON_CTRL1[TCON_EN]='0' and TCON_CTRL1[TCON_BYPASS]='1'.

58.4.2 Timing signal generator

The Timing Signal Generator (TSG) is the TCON timing signal generation unit. It accepts the HSYNC/VSYNC signals from the input parallel display interface, and maintains two counters (*hcount, vcount*) based on that. All the timing signals are generated based on these two counters.

For every line the *hcount* counts the current pixel number, from 1 to the number of pixels per line (the full line, including inactive period). It restarts from 1 with the HSYNC signal rising edge.

Similarly the *vcount* counts from 1 with the VSYNC signal rising edge (first line), increments by "1" at the end of each line, until the last line in a frame (including inactive lines).

The timing signal generator is composed of 4 comparators (Comparator), 6 pulse generators (Pulse generator), 1 toggle generator (Toggle generator), and a signal mixer or synthesizer (Signal Mixer (SMX)). See the following sections for detailed descriptions.

58.4.2.1 Comparator

There are 4 comparators in the TCON, each can be configured to compare *hcount* or *vcount* with the value specified in a TCON_COMPx Register. If desired the user can mask some bits from comparing by setting the corresponding bits in both TCON_COMPx_MSK and TCON_COMPx register to "0". A one-cycle (pixel clock cycle, or line cycle) pulse will be generated when the compare result is match, and the comparison logic is shown below:

$$compare\_out = (TCON\_COMPx.COMP\_VALUE == (TCON\_COMPx\_MSK.MASK \ \& \ hcount))$$

or

$$compare\_out = (TCON\_COMPx.COMP\_VALUE == (TCON\_COMPx\_MSK.MASK \,\&\, vcount))$$

TCON_COMPx[FUNC_SEL] determines which of the above equations is used (i.e. comparison is done on horizontal or vertical direction).

58.4.2.2 Pulse generator

There are 6 pulse generators in the TCON which can be used to generate pulses which have a *set* point and a *reset* point, and the pulse length is discretional. The *set* and *reset* point is determined by TCON_PULSEx[SET] and TCON_PULSEx[RESET], to which the *hcount* or *vcount* value will be compared. If desired the user can mask some bits from comparing by setting the corresponding bits in both TCON_PULSEx_MSK and TCON_PULSEx register to 0. The equations used to find the *set/clear* point are similar to the equations given in the "Comparator" section above.

TCON_PULSEx[FUNC_SEL] controls the type of the pulse, a.k.a. whether the *set/reset* point comparison is performed on horizontal direction (compare with *hcount*) or vertical direction (compare with *vcount*). And when vertical comparison is selected (ie. FUNC_SEL = 01 or 11), 1 of the 4 comparator outputs (must be a horizontal pulse) can be selected to further determine the signal transition point on horizontal direction. Or when FUNC_SEL = 10, the signal transition will happen immediately when the vertical compare matches (i.e. at the beginning of the line). When needed TCON_PULSEx[COMPARATOR_SEL] selects 1 of the 4 comparator outputs as the horizontal reference.

58.4.2.3 Toggle generator

There is a toggle generator in the TCON that can be used to generate signals which toggles line to line, or frame to frame, or signal which toggles line to line but polarity changes from frame to frame. The toggle generator accepts the 4 comparator outputs (TCON_COMP[0:3]) and the 6 pulses (TCON_PULSE[0-5]), and generates 4 toggle signals (vtgl*[0-3]*) based on that.

The toggle generator uses a counter (vtgl_counter) and a T flip-flop to generate the 4 toggle signals. The vtgl_counter takes 1 of the 4 comparator outputs as the clock (*h_ref*), and 1 of the 6 pulses as the enable signal (*v_ref*). The *h_ref/v_ref* selection is controlled via TCON_CTRL1[H_REF_SEL] and TCON_CTRL1[V_REF_SEL]. TCON_CTRL1[VLEN] sets the maximun counter value. The vtgl_counter increments at

the rising edge of *h_ref* when *v_ref* is high, and it falls back to "0" when the counter value exceeds VLEN. And then the vtgl*[0-2]* are generated by decoding the counter value via the following equations.

$$vtgl[0] = (vtgl\_counter == 0)$$

$$vtgl[1] = (vtgl\_counter == 1)$$

$$vtgl[2] = (vtgl\_counter == 2)$$

The H_REF_SEL and V_REF_SEL shall be programmed so that the *h_ref* is a horizontal pulse (one pixel clock cycle pulse per line) and the *v_ref* is a vertical pulse (pulse lasts for 1 line or several lines). The following table shows the relationship between vlen, vtgl_counter sequence and vtgl[2:0].

Table 58-165. vtgl[0-2] sequence

INPUT	OUTPUT	vtgl_counter sequence								
vlen	vtgl	0	1	2	3	4	5	6	7	8
0	0	1	1	1	1	1	1	1	1	1
	1	0	0	0	0	0	0	0	0	0
	2	0	0	0	0	0	0	0	0	0
1	0	1	0	1	0	1	0	1	0	1
	1	0	1	0	1	0	1	0	1	0
	2	0	0	0	0	0	0	0	0	0
2	0	1	0	0	1	0	0	1	0	0
	1	0	1	0	0	1	0	0	1	0
	2	0	0	1	0	0	1	0	0	1

A T flip-flop is used to generate vtgl[3]. T flip-flop is a type of flip-flop whose output toggles (inverts) at the rising edge of the clock input when the enable signal input is high. The T flip-flop in the toggle generator is clocked by *h_ref*, and the enable signal (*en*) is the bit-AND of vtgl*[0]* and *v_ref*.

By programming the VLEN, and control the pulse length of v_ref, the vtgl[3] can be used to generate toggle signals whose polarity changes from frame to frame. See the table below for some programming examples.

Table 58-166. vtgl[3] programming examples

vtgl[3]	v_ref pulse length	vlen
toggles every line, polarity inverts frame to frame, steady during vertical blanking (2 frame sequence)	odd (eg. number of active lines + 1)	0
toggles every other line, polarity inverts frame to frame, steady during vertical blanking (2 frame sequence)	odd*2 (eg. number of active lines)	1

Table continues on the next page...

Table 58-166. vtgl[3] programming examples (continued)

vtgl[3]	v_ref pulse length	vlen
toggles every 3rd line, polarity inverts frame to frame, steady during vertical blanking (2 frame sequence)	odd*3 (eg. number of active lines + 3)	2
toggles every other line, walking pattern (4 frame sequence)	odd (eg. number of active lines + 1)	1

To make it easier to understand, the following table shows a simpler example where the number of active lines is 6.

Table 58-167. ctgl[3] signal example A

VLEN	Frame	Active Line Number									v_ref pulse length
		0	1	2	3	4	5	6	7	8	
0	0	0	1	0	1	0	1	0			7
	1	1	0	1	0	1	0	1			7
1	0	0	1	1	0	0	1				6
	1	1	0	0	1	1	0				6
2	0	0	1	1	1	0	0	0	1	1	9
	1	1	0	0	0	1	1	1	0	0	9
1	0	0	1	1	0	0	1	1			7
	1	0	0	1	1	0	0	1			7
	2	1	0	0	1	1	0	0			7
	3	1	1	0	0	1	1	0			7

58.4.2.4 Signal Mixer (SMX)

To generate more complicated timing signals, there are 14 Signal Mixer/Synthesizer (SMX) modules in the TCON which can be used to perform logic operations between every two signals. Each SMX module takes 2 signal inputs (X and Y), and generates 1 SMXx output.

The X and Y input of each SMX module can be selected from any two of the 28 signals (4 comparator outputs, 6 pulses, 4 toggle generator outputs, constant 0 or 1, and 12 feedback signals SMX0~11). The X/Y signal selection is configurable via TCON_SMXx[X_SEL] and TCON_SMXx[Y_SEL]. 12 of the SMXx output (SMX0~11) can be feedback to the SMXx input again in order to generate even more complicated signals (combining information of more than 2 signals),

The SMX module is composed of several logic operation units (AND, OR, XOR or NAND), and a look-up-table (LUT).

The LUT takes 4 inputs, including the current LUT output value and a 4-bit index (index[3:0]), the LUT output is the next cycle SMX output. Function performed by the LUT is determined by the values programmed into TCON_LUTx. By default the value of TCON_LUTx is 32'hffff_005c and the default truth table of the LUT is shown in the following table where SMXx(n-1) is the current SMXx state and SMXx(n) is the next cycle SMXx value. With this setting the LUT emulates the function of a Set/Reset/Toggle/Data flip-flop, where index3 to index0 are the Set/Reset/Toggle enable/Data inputs, "Set" has the highest priority. The user can also reprogram the TCON_LUTx registers so that the LUT performs different operations (e.g. change the priority order of the Set/Reset/Toggle enable/Data signals).

The index[3:0] input of the LUT is generated by the logic operation units. Each bit of it is a logic operation of X, Y, 0 or 1. The logic operations performed are selected by TCON_SMXx[INDEX0-3_SEL].

Table 58-168. Default TCON LUT Truth Table

index3	index2	index1	index0	SMXx(n-1)	SMXx(n)
1	x[1]	x	x	x	1
0	1	x	x	x	0
0	0	1	x	0	1
0	0	1	x	1	0
0	0	0	1	x	1
0	0	0	0	x	0

1. Don't care

58.4.2.5 Output Crossbar Mux

The output crossbar mux is used to select 12 from the generated 20 timing signals as the 12 TCON timing signal outputs. The 20 timing signals include: 6 pulses, 4 toggle generator outputs (vtgl[0:3]), constant "0" and "1", and 8 of the 14 SMXs output (SMX6~13). TCON_OMUX_HIGH and TCON_OMUX_LOW determines which 12 timing signals are selected as the output.

58.4.3 Bit Mapping Control (BMC)

The Bit Mapping Control (BMC) module is adopted to remap the color component order, color bit order and output clock position. The following figure shows the diagram of the bit mapping control module.

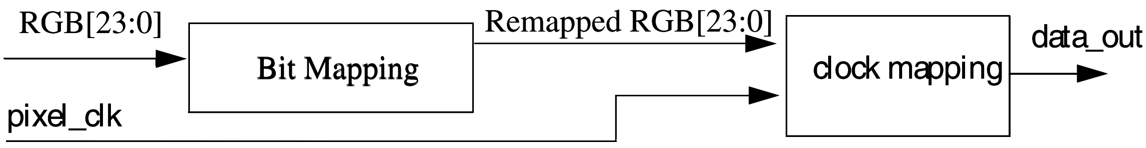

Figure 58-160. Bit mapping control

58.4.3.1 Bit mapping in TTL mode

The default bit mapping in 8-bit color mode is given in the following table.

Table 58-169. TTL mode bit mapping, 8-bit color

data signal	Rising of pix_clk
Remapped RGB[23:16]	{R7,R6,R5,R4,R3,R2,R1,R0}
Remapped RGB[15:8]	{G7,G6,G5,G4,G3,G2,G1,G0}
Remapped RGB[7:0]	{B7,B6,B5,B4,B3,B2,B1,B0}

The default bit mapping in 6-bit colour mode is given in the following table:

Table 58-170. TTL mode bit mapping, 6-bit color

data signal	Rising of pix_clk
Remapped RGB[23:16]	{R7,R6,R5,R4,R3,R2,2'b0}
Remapped RGB[15:8]	{G7,G6,G5,G4,G3,G2,2'b0}
Remapped RGB[7:0]	{B7,B6,B5,B4,B3,B2,2'b0}

Besides the default bit mapping, it is possible to swap the RGB color component order (TCON_BMC[COLOR_ORDER]) and the LSB/MSB bit order in each color component (TCON_BMC[BIT_ORDER]).

58.4.3.2 Bit mapping examples

TTL mode; below settings will remap the bit order as given in the following table.

TCON_BMC[COLOR_ORDER] = 3'b000; //color order RGB

TCON_BMC[BIT_ORDER] = 1; //0 up to MSB7

TCON_CTRL1[COLOR_DEPTH] = 1; //6bit per color;

Table 58-171. Bit mapping example

Data signal	Rising of pix_clk
Remapped RGB[23:16]	{R2,R3,R4,R5,R6,R7,2'b0}
Remapped RGB[15:8]	{G2,G3,G4,G5,G6,G7,2'b0}
Remapped RGB[7:0]	{B2,B3,B4,B5,B6,B7,2'b0}

58.4.3.3 Clock mapping in TTL mode

It is possible to assign the pixel clock output to any bit of the data_out[1:25] in TTL mode, configured via TCON_BMC[CLK_POS]. See the table below for details. The data_out pins are represented on the rows of the table with the number of the pin being in the left hand column. The selected function for that pin is indicated in the row by the CLK_POS value (0 to 24). For example, if CLK_POS = 10 then the function on data_out[11] is clock; if CLK_POS < 10 then data_out[11] is RGB[9]; if CLK_POS > 10 the data_out[11] is RGB[10]

Table 58-172. Clock mapping in TTL mode

</table>

1. CLOCK
2. n stand for remapped rgb[n]

58.4.4 Clock/Data Skew Adjustment

In order to fulfill different setup/hold timing requirements on the output interface, it is possible to adjust the signal skew between the pixel clock output and the data output (including RGB data and timing signals). The output pixel clock can be flexibly shifted compared to the the data signals. It can be shifted over the whole pixel clock period with a granularity of half of the source pixel clock period (the clock from which the pixel clock is derived/divided).

TCON_CTRL2[DIV_RATIO] configures the pixel clock divide ratio, and TCON_CTRL2[CLK_OFFSET] configures the offset between the internal pixel clock and the output pixel clock.

58.5 Initialization/Application Information

This section discusses TCON initialization and startup.

58.5.1 TCON Initialization

The procedure to bring up the TCON out of reset state and start data and timing signal generation:

1. Program TCON_COMPx and TCON_COMPx_MSK registers to configure the comparator.
2. Program TCON_PULSEx and TCON_PULSEx_MSK registers to configure the pulse generator.
3. Program TCON_SMXx and TCON_LUTx registers if necessary.
4. Program TCON_BMC register to configure the bit mapping control.
5. Program the TCON_CTRL1 register to configure the operation mode of TCON and enable TCON (It is recommended to do this in two steps, and set TCON_EN in the second).

Chapter 59
Run Length Encoding Decoder RLE_DEC

59.1 Introduction

The RLE_DEC module is used to decode data that has been compressed using a Run Length Encoding (RLE) scheme. It has input and output FIFO buffers directly connected to the crossbar switch and requires the CPU or DMA to push in the encoded data and then extract the decoded result. The module configuration is optimized for decoding data stored in a two-dimensional image format but can also be used to extract data stored as a linear array.

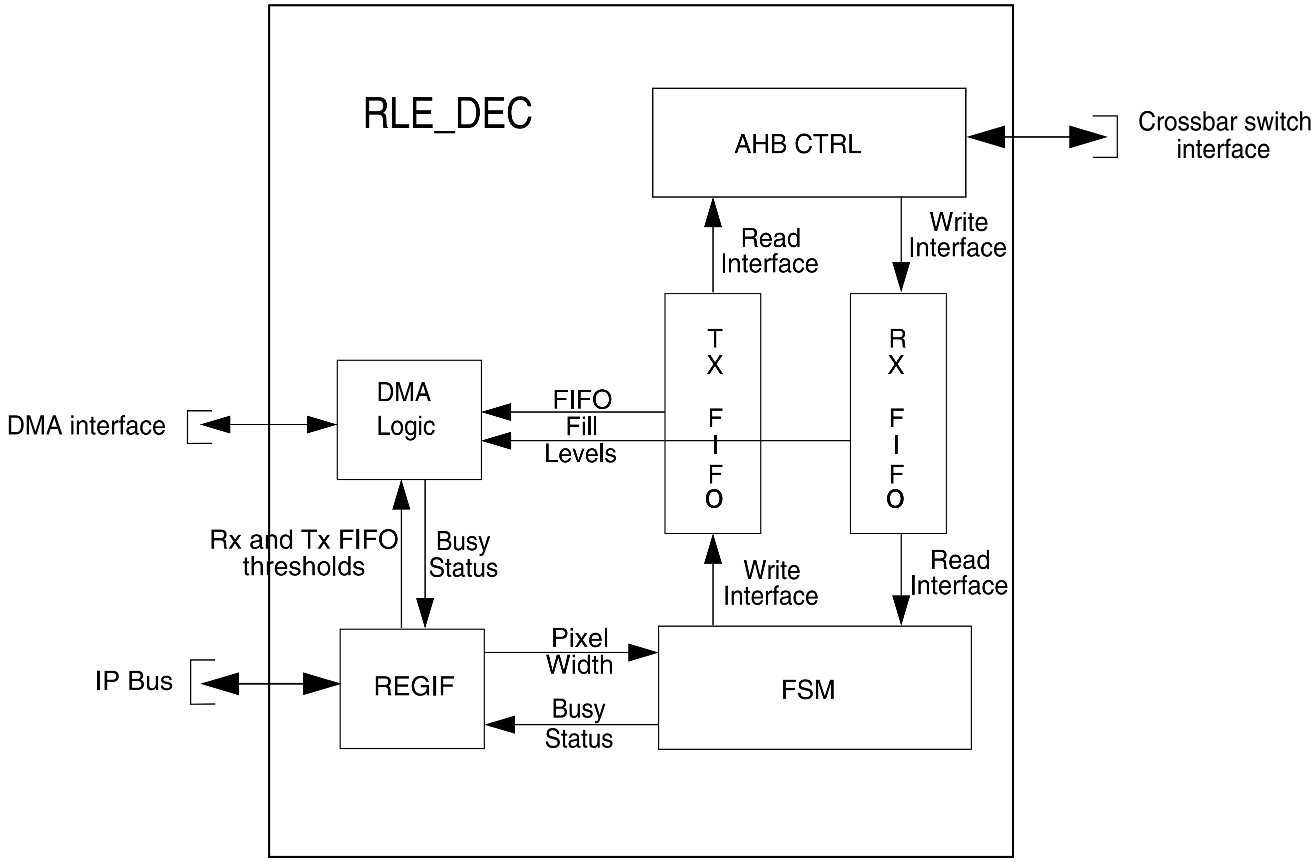

Figure 59-1. RLE_DEC Block Diagram

59.1.1 Overview

The above figure is a block diagram of the Run Length Encoding Decoder (RLE_DEC) module. The module has two independent interfaces that are memory mapped into the device:

- Crossbar switch interface for moving data into and out of the module
- IP bus interface for configuring the module

The crossbar interface appears in the device memory map as two FIFOs. Writes to the Rx FIFO will cause the RLE_DEC to begin decoding operations. The RLE_DECs Finite State Machine (FSM) removes data from the Rx FIFO, decodes it and places the output into the Tx FIFO. The decoded data appears in the Tx FIFO and is removed from this FIFO after it is read by a crossbar master such as the CPU or eDMA. The DMA operations require the use of two different DMA channels.

The module is configured and its status monitored using registers on the IP bus that appear as locations in the module register memory area. This configuration includes information on the size of the image (or data set) and the size of the individual pixels (or data elements) in the image. The RLE_DEC uses this information to determine when an operation is complete. For this reason the RLE_DEC will typically be reconfigured for each operation since the size of each compressed image will be different.

The module can raise interrupts to indicate errors and when an operation is complete.

59.1.2 Features

The RLE_DEC supports the following features:

- Lossless decompression
- Pixel formats supported: 8bpp, 16bpp, 24bpp and 32bpp (Programmable)
- AHB mapped Rx FIFO (8x8 bytes deep) with DMA support.
- AHB mapped Tx FIFO (8x8 bytes deep) with DMA support.
- Programmable fill levels of read and write buffers for initiating burst transfers.
- Partial Image Decode feature, wherein only a portion of the decoded image is given as output. (See id-Image_Co-ordinates_Description for details).
- Support for Stop Mode for power-saving purposes

59.1.3 RLE_DEC Modes of Operation

This section describes the modes of operation.

59.1.3.1 Normal Mode

In this mode, the RLE_DEC block performs the normal 'Run Length Encoding' Decode operation. Further details about this mode of operation can be found in chapter Normal Mode.

59.1.3.2 Module Disable Mode

The Module Disable Mode is used for power management of the device containing the RLE_DEC module. It is controlled by signals external to the RLE_DEC. The clock to the non-memory mapped logic in the RLE_DEC can be stopped while in the Module Disable Mode. See Module Disable Mode.

59.1.3.3 Stop Mode

The Stop Mode is used for power management by the system mode management. When a request is made to enter Stop Mode, the RLE_DEC block completes the action currently processed. Then the request is acknowledged.

59.2 External Signal Description

RLE_DEC has no external signals.

59.3 Interrupt and DMA Request Signals

The interrupt and DMA request lines of the RLE_DEC module are mapped to the internal flags in the DEC_RLE_ISR register.

59.4 Memory map and register definition

The memory map for the RLE_DEC module is given below. The total address for each register is the sum of the base address for the RLE_DEC module and the address offset for each register. Also, please note that the bit order for each register bit field is [highest:lowest], whereas the overall register bits are numbered [lowest:highest].

RLE_DEC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4004_2000	Module Configuration Register (RLE_DEC_MCR)	32	R/W	2020_0009h	59.4.1/3363
4004_2004	Image Configuration Register (RLE_DEC_ICR)	32	R/W	0000_0000h	59.4.2/3364
4004_2008	Compressed Image Size Register (RLE_DEC_CISR)	32	R/W	0000_0000h	59.4.3/3365

RLE_DEC_MCR field descriptions

Field	Description
31–24 RX_FIFO_ THRESHOLD	Rx FIFO threshold: This field determines how much space should be available for writing into the Rx Buffer until the write action is triggered (through DMA). When the number of bytes of available space in RX FIFO exceeds the number given by this field the RLE_DEC_FR[RFFR] flag is asserted.
23–16 TX_FIFO_ THRESHOLD	Tx FIFO threshold: This field determines how many entries must be read into the TX FIFO until the readout action is triggered. When the number of valid entries in the TX FIFO exceeds the number given by this field the RLE_DEC_FR[TFDR] flag is asserted.
15–4 RESERVED	This field is reserved.
3 GRLE_EN	Enable Gradient RLE decoding This bit enables or disables Gradient RLE decoding. Gradient RLE is described in detail in the section, RLE encoding format. 0 Disables the Gradient RLE decoding. Decoding is performed only as traditional RLE. 1 Enables the Gradient RLE decoding. Decoding can be done according to either Gradient RLE or traditional RLE algorithm, based on the decoding of Command Byte.
2 TXFFEN	Tx FIFO Flush Enable. This bit configures the operation of the RLE Decoder in the case when the image decoding is complete and the data remaining in the Tx FIFO is below the value of TX_FIFO_THRESHOLD. 0 Trigger the DMA action only when TxFIFO has more data than TX_FIFO_THRESHOLD. 1 Trigger the DMA action until the Tx FIFO is empty even if it is less than TX_FIFO_THRESHOLD.
1 RESERVED	This field is reserved.
0 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the RLE_DEC to be stopped, putting the RLE_DEC in a software controlled power-saving state. See the "Module Disable Mode" section for more information. 0 Enable RLE_DEC clocks. 1 Allow external logic to disable RLE_DEC clocks.

59.4.2 Image Configuration Register (RLE_DEC_ICR)

The RLE_DEC_ICR holds configuration data associated with configuration of image parameters. This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004_2000h base + 4h offset = 4004_2004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved

1–0 WIDTH	00 Pixel Width is 08-bits; 01 Pixel Width is 16-bits; 10 Pixel Width is 24-bits; 11 Pixel Width is 32-bits.

59.4.3 Compressed Image Size Register (RLE_DEC_CISR)

The RLE_DEC_CISR holds the size of the compressed image. This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004_2000h base + 8h offset = 4004_2008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RLE_DEC_CISR field descriptions

Field	Description
31–0 SIZE	This is the byte-size of compressed image, that will be given as an input to the RLE DEC. This should be programmed before the Module is enabled using MDIS.

59.4.4 Decompressed Image Co-ordinates register (RLE_DEC_DICR)

The RLE_DEC_DICR holds the final coordinates of the decompressed image. Decompression is done until this pixel reached. Please refer to section "Image Coordinates' Description". This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004_2000h base + Ch offset = 4004_200Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RLE_DEC_DICR field descriptions

Field	Description
31–16 X	This is the X Co-ordinate of the final pixel of the decompressed image, that will be given as the output of the RLE DECODER. This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.
15–0 Y	This is the Y Co-ordinate of the final pixel of the decompressed image, that will be given as the output of the RLE DECODER. This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.

59.4.5 Status Register (RLE_DEC_SR)

The RLE_DEC_SR register provides the status information about the TX FIFO and RX FIFO.

Address: 4004_2000h base + 10h offset = 4004_2010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																RXFREE								TXFILL							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RLE_DEC_SR field descriptions

Field	Description
31–16 RESERVED	This field is reserved.
15–8 RXFREE	This status gives the amount of free space in bytes, available in Rx FIFO to write.
7–0 TXFILL	This status gives the amount of data in bytes, available in Tx FIFO to read.

59.4.6 Interrupt Request Status Register (RLE_DEC_ISR)

The RLE_DEC_ISR register is the Interrupt Status Register for RLE DECODER. The interrupts are asserted upon associated events. They are deasserted upon write to this register.

Address: 4004_2000h base + 14h offset = 4004_2014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RLE_DEC_ISR field descriptions

Field	Description
31–8 RESERVED	This field is reserved.
7 RXDIF	Rx Image Done. Is asserted when the amount of received data has equalled the programmed "Compressed Image Size Register"
6 TXDIF	Tx Image Done. Is asserted when coordinates of decompressed image cross End Pixel Coordinates which are defined in "End Pixel Coordinate Register"
5 RXUIF	Rx FIFO has space. Asserted when Rx FIFO has more space than Rx FIFO Threshold. (DMA request for input data.)
4 TXUIF	Tx FIFO has data. Asserted when Tx FIFO has more data than Tx FIFO Threshold. (DMA request for output data.)
3 RXFIF	Rx FIFO Full: Asserted when Rx FIFO has no more space left for data and a write was attempted on it.
2 TXFIF	Tx FIFO Full: Asserted when Tx FIFO has no more space left for data and a write was attempted on it.

Table continues on the next page...

RLE_DEC_ISR field descriptions (continued)

Field	Description
1 RXEIF	Rx FIFO Empty: Asserted when Rx FIFO has no data and a read was attempted from it.
0 TXEIF	Tx FIFO Empty: Asserted when Tx FIFO has no data and a read was attempted from it.

59.4.7 Interrupt Request Enable Register (RLE_DEC_RIER)

The RLE_DEC_RIER register provides enables for the interrupts in the RLE_DEC module.

Address: 4004_2000h base + 18h offset = 4004_2018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RLE_DEC_RIER field descriptions

Field	Description
31–8 RESERVED	This field is reserved.
7 RXDIE	Interrupt Enable for Rx Image Done Interrupt
6 TXDIE	Interrupt Enable for Tx Image Done Interrupt
5 RXUIE	Interrupt Enable for Rx FIFO has space Interrupt
4 TXUIE	Interrupt Enable for Tx FIFO has data Interrupt
3 RXFIE	Interrupt Enable for Rx FIFO full Interrupt
2 TXFIE	Interrupt Enable for Tx FIFO full Interrupt

Table continues on the next page...

RLE_DEC_RIER field descriptions (continued)

Field	Description
1 RXEIE	Interrupt Enable for Rx FIFO empty Interrupt
0 TXEIE	Interrupt Enable for Tx FIFO empty Interrupt

59.4.8 Start Pixel Co-ordinate Register of Image (RLE_DEC_SPCR)

The RLE_DEC_SPCR holds the start coordinates of the decompressed image. This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004_2000h base + 1Ch offset = 4004_201Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RLE_DEC_SPCR field descriptions

Field	Description
31–16 X	This is the X Co-ordinate of the first pixel of the decompressed image, that will be given as the output of the RLE DECODER. Please refer to section "Image Coordinates' Description". This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.
15–0 Y	This is the Y Co-ordinate of the final pixel of the decompressed image, that will be given as the output of the RLE DECODER. Please refer to section "Image Coordinates' Description". This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.

59.4.9 End Pixel Co-ordinate Register of Image (RLE_DEC_EPCR)

The RLE_DEC_SPCR holds the end co-ordinates of the decompressed image of interest. Please refer to section "Image Coordinates' Description". This register can be accessed with 8-bit, 16-bit and 32-bit wide operations.

Address: 4004_2000h base + 20h offset = 4004_2020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	X																Y

RLE_DEC_EPCR field descriptions

Field	Description
31–16 X	This is the X Co-ordinate of the last pixel of the decompressed image of interset, that will be given as the output of the RLE DECODER. Please refer to section "Image Coordinates' Description". This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.
15–0 Y	This is the Y Co-ordinate of the last pixel of the decompressed image of interset, that will be given as the output of the RLE DECODER. Please refer to section "Image Coordinates' Description". This should be programmed before the Module is enabled using MDIS. This field has a minimum value of 1.

59.4.10 Crossbar Switch Bus Register Memory Map

The table below shows the Rx and Tx FIFOs of the RLE_DEC mapped to the Crossbar switch (AHB) interface.

Table 59-11. RLE_DEC AMBA Bus Memory Map

Address	Register Name
RLE_DEC-AMBA_BASE + 0x0000_0000 to RLE_DEC-AMBA_BASE + 0x0000_0038	Rx FIFO address range:- The AHB master can read from and write into these addresses (For Debug purposes only). The FIFO operation is performed only when the access is made to the below mentioned Memory Mapped Area for Rx FIFO.
RLE_DEC-AMBA_BASE + 0x0000_0040 to RLE_DEC-AMBA_BASE + 0x0000_0078	Tx FIFO address range:- The AHB master can read from and write into these addresses (For Debug purposes only). The FIFO operation is performed only when the access is made to the below mentioned Memory Mapped Area for Tx FIFO.
RLE_DEC-AMBA_BASE + 0x0000_0080 to RLE_DEC-AMBA_BASE + 0x0000_00B8	Memory Mapped Area for Rx FIFO. AHB can only Write into this address. A write into this address results in a write to the Rx FIFO wherever the write pointer points. If Rx FIFO is full, AHB write request will result in HREADY low, unless space is there for the write operation. (Please Note: The write(burst or single write) should start from address (RLE_DEC_AMBA_BASE + 0x0000_0080) only.)
RLE_DEC-AMBA_BASE + 0x0000_00C0 to RLE_DEC-AMBA_BASE + 0x0000_00F8	Memory Mapped Area for Tx FIFO. AHB can only Read from this address. A read into this address results in a read from the top of the Tx FIFO. If Tx FIFO is empty, AHB Read request will result in HREADY low, unless some data is available for reading. (Please Note: The read(burst or single read) should start from address (RLE_DEC_AMBA_BASE + 0x0000_00C0) only.)

59.4.11 Crossbar switch memory map descriptions

This section describes the Rx and Tx FIFO address mapping.

59.4.11.1 Rx FIFO Address Range

The size Rx FIFO is 8-bytes X 8-bytes. The Rx FIFO address range is (RLE_DEC_AMBA_BASE address + 0x0000) to (RLE_DEC_AMBA_BASE address + 0x0038). A crossbar switch can read from and write into these addresses (For Debug purposes only). The FIFO operation is performed only when the access is made to the below mentioned Memory Mapped Area for Rx FIFO.

59.4.11.2 Tx FIFO Address Range

The size Tx FIFO is 8-bytes X 8-bytes. The Tx FIFO address range is (RLE_DEC_AMBA_BASE address + 0x0040) to (RLE_DEC_AMBA_BASE address + 0x0078). A crossbar switch can read from and write into these addresses (For Debug purposes only). The FIFO operation is performed only when the access is made to the below mentioned Memory Mapped Area for Tx FIFO.

59.4.11.3 Memory Mapped Rx FIFO

The contents of Rx FIFO are mapped to (RLE_DEC_AMBA_BASE address + 0x0080). Writing RLE compressed data into the Rx FIFO increments the write-pointer based on the size of the written data.

The RLE decode process can be automated by using the eDMA. Each time the free space of Rx FIFO exceeds a certain level (programmable), a (Rx FIFO) DMA request is asserted. When enabled the eDMA can be used to write RLE compressed data into the Rx FIFO.

A read request to Rx FIFO results in an error.

59.4.11.4 Memory Mapped Tx FIFO

The contents of Tx FIFO are mapped to (RLE_DEC_AMBA_BASE address + 0x00C0). The RLE_DEC module writes decompressed data into the Tx FIFO.

The RLE decode process can be automated by using the eDMA. Each time the contents of the Tx FIFO exceeds a certain fill-level (programmable), a (Tx FIFO) DMA request is asserted. When enabled the eDMA can be used to read the decompressed data from the Tx FIFO.

A write request to Tx FIFO results in an error.

59.5 Functional Description

This section describes the module functions.

59.5.1 RLE encoding format

In the traditional RLE encoding format, the expected encoding is as follows:

- The first data byte in the encoded image is a command byte (CMD[7:0]).
- The ms bit (CMD[7]) indicates if the following bytes are raw or compressed pixels. One pixel can be 8-bit, 16-bit, 24-bit or 32-bit wide, depending on the PIXEL_WIDTH configuration.
- The remaining 7 command bits (CMD[6:0]), specify the "count", i.e. the number of raw or compressed pixels that follow the command byte. The count is offset by 1. Value 0 means count is 1. Value 1 means count is 2, and so on.
- For compressed pixels (CMD[7] = 1), only one pixel follows the command byte. This pixel is repeated count+1 times. A new command follows after CMD+(1*{Pixel width}) pixels.
- For raw pixels (CMD[7] = 0), count+1 number of pixels follow the command byte and these are passed to the Tx FIFO as is.
- If there is more data to decode then a new command follows after CMD+({count +1}*{Pixel width}) bytes. This encoding continues until the whole image is decoded.

In the gradient RLE encoding format, the expected encoding is as follows:

- The first data byte in the encoded image is a command byte (CMD[7:0]).
- For raw pixels (CMD[7] = 0), the encoding is same as traditional RLE.
- For compressed pixels (CMD[7] = 1), the remaining 7 command bits (CMD[6:0]) (or the "count") are used to differentiate between traditional and gradient RLE. If the count is non-zero, the encoding is treated as tradional RLE. If the count is zero, the encoded data is in Gradient RLE format.
- If the encoded data is in Gradient RLE format, the second byte represents the decoded sequence length. If the value of second byte is X, then the decoded sequence length is X+3 pixels. (X+3 is the length of the generated output sequence).

- The pixel that follows represents the first pixel of the decoded sequence. And the pixel after that is the delta. The delta bytes are signed 8-bit fixed point numbers. The second pixel of the decoded sequence is calculated by adding adding delta to the first pixel. The third pixel of the decoded sequence is calculated by adding adding delta to the second pixel, and so on.
- The adding of delta to the pixels is done with help of accumulators. The pixel bytes are loaded into 14-bit accumulators at the MSB. The LSB 6-bits of the accumulatora are 0s. The delta are added to respective accumulators. The MSB 8-bits of the accumulators form the next pixel.

59.5.2 RLE decoding process

The recommended process to decode the data is as follows:

- The RLE_DEC module is disabled by default (MDIS=1).
- Before enabling the device, program the compressed image size register (RLE_DEC_CISR) and decompressed image size register (RLE_DEC_DICR) for the image. The decoder expects to read compressed-image-size amount of bytes from the Rx FIFO and expects to decode and write decompressed-image-size amount of bytes into the Tx FIFO.
- When less than the full image is to be decoded then configure the Start Pixel Coordinates Register (RLE_DEC_SPCR) and the End Pixel Coordinates Register (RLE_DEC_EPCR).
- Configure the WIDTH of the pixels in the image (RLE_DEC_ICR).
- Enable the RLE_DEC DMA Rx and Tx channels in the DMAMUX module and connect these to channels in the eDMA. Configure the selected eDMA channels such that the compressed image is written into the Rx FIFO and the decompressed image is copied from the Tx FIFO.
- Enable the RLE_DEC by setting MDIS=0.
- When the decoding is complete the TXDIF flag is set (RLE_DEC_ISR register). This indicates that the RLE process is complete but depending on the size of the image and the value of the RLE_DEC_MCR[TXFFEN] bit there may be some decoded pixels that have not yet been copied from the Tx FIFO because its threshold has not been reached.

- If the TXFFEN bit is not set to automatically flush the Tx FIFO then trigger an eDMA transfer under software control until the Tx FIFO is empty (TXFILL=0 in RLE_DEC_SR register).
- Set MDIS=1 to disable the module. The module needs to be disabled at the end of image decompression and enabled again only after the parameters of the new image have been programmed.

59.5.3 Image coordinates' example

The following figure shows the definition of the coordinates used in RLE_DEC to define the decompressed image.

Let the decompressed image be of size 10-pixels x 10-pixels. The start coordinate is the coordinate at the top-left corner, (1,1), i.e. X=1 and Y=1. The last coordinate is the bottom-right coordinate, (10,10) in this case. So, we see that the image size can be described by the bottom-right coordinate of the image. This pixel coordinate is described in the register "Decompressed Image Coordinate Register".

If only a part of the complete image is to be given as output, then "Start Pixel Coordinate Register" and "End Pixel Coordinate Register" should be programmed appropriately. For example, in the figure shown below, if the gray area is the image of interest and it is only required to output only that part of the decompressed image, then the "Start Pixel Coordinate Register" should be programmed as (X=3, Y=4) and "End Pixel Coordinate Register" should be programmed as (X=7, Y=7).

If however, the complete decompressed image is to be output, then the "Start Pixel Coordinate Register" should be programmed as (X=1, Y=1) and "End Pixel Coordinate Register" should be programmed as (X=10, Y=10), i.e. equal to "Decompressed Image Coordinate Register".

Table 59-12. Decompressed 10x10 pixel image

(1,1)	(2,1)	(3,1)	(4,1)	(5,1)	(6,1)	(7,1)	(8,1)	(9,1)	(10,1)
(1,2)

(1,7)						(7,7)			
(1,8)									
(1,9)									
(1,10)									(10,10)

59.5.4 Modes of Operation

The possible operational modes of the RLE_DEC block are:

- Normal Mode: This is used for normal RLE decompression of data received from AHB interface. The module enters this mode by deasserting RLE_DEC_MCR[MDIS].
- Stop Mode: The mode used by the system when changing modes if the RLE is no longer required. When the system requests Stop Mode, the RLE_DEC block completes the execution of the current command and acknowledges the request. The system then removes clocks to the RLE_DEC block.
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the RLE_DEC can be stopped while in Module Disable Mode. The module enters the mode by setting RLE_DEC_MCR[MDIS].

59.5.5 Normal Mode

In normal mode, decompression of data is performed using RLE scheme. The module enters this mode by deasserting RLE_DEC_MCR[MDIS].

Whenever the Rx FIFO has some data, the state machine is triggered. The decoding operation starts according to the RLE decoding scheme described above. Whenever Tx FIFO is not full and Rx FIFO has got data to transmit, the decoding is done.

After completing the decode of one image, the Normal mode should be exited. For decoding the data of next image, the re-entry to Normal mode should be done only after the new image parameters have been programmed.

59.5.6 Power Saving Features

The RLE_DEC supports the following power-saving strategies:

- Stop Mode
- Module Disable Mode

59.5.6.1 Module Disable Mode

The RLE_DEC block is in Module Disable Mode by default. It is exited to Normal-Mode by de-asserting the MDIS bit in RLE_DEC_MCR register.

Host software can initiate Module Disable Mode by writing a '1' to the MDIS bit. When a request is encountered to enter Module Disable Mode, the RLE_DEC negates clock-enable when it is ready to enter the Module Disable Mode.

If implemented, the clock-enable signal can stop the clock to the non-memory mapped logic. When clock-enable is negated, the RLE_DEC is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the RLE_DEC is in the Module Disable Mode. DMA request signals cannot be cleared while in the Module Disable Mode.

Note that issuing a new AHB request is illegal in Normal Mode during the time starting with raising the request to enter Module Disable Mode and ending with leaving the Module Disable Mode.

Chapter 60
Video subsytem

60.1 Introduction

The video subsystem consists of an analog video front end (AFE), a digital video decoder, and video interface unit. The AFE accepts NTSC or PAL input from a device such as an analog camera. The video decoder provides YUV888-formatted data to the the video interface unit (VIU).

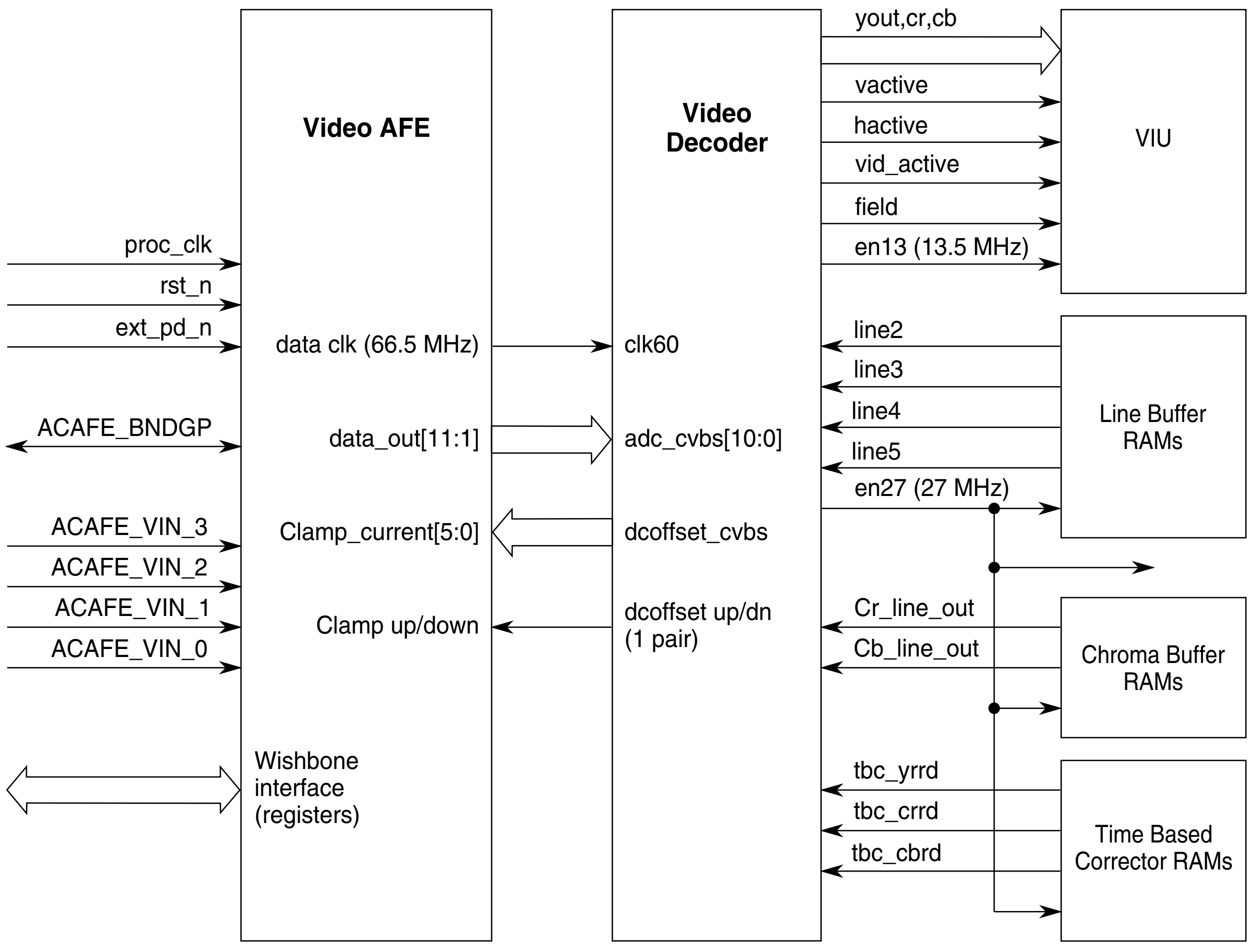

Figure 60-1. Video subsystem block diagram

60.2 External signal description

The following table is a list of signals driven by external pins.

Table 60-1. Video subsystem external signals

Name	Module	Description	Input/ Output
VADCSE0	Video AFE	Composite video input 0	Input
VADCSE1	Video AFE	Composite video input 1	Input
VADCSE2	Video AFE	Composite video input 2	Input
VADCSE3	Video AFE	Composite video input 3	Input
VADC_AFE_BANDGAP	Video AFE	Band gap decoupling	Input/Output

60.3 Analog front end (AFE)

The analog front end (AFE) digitizes an analog video signal such as from an inexpensive analog camera. The video signal can be selected from one of four inputs, VIN0-VIN3, through register control.

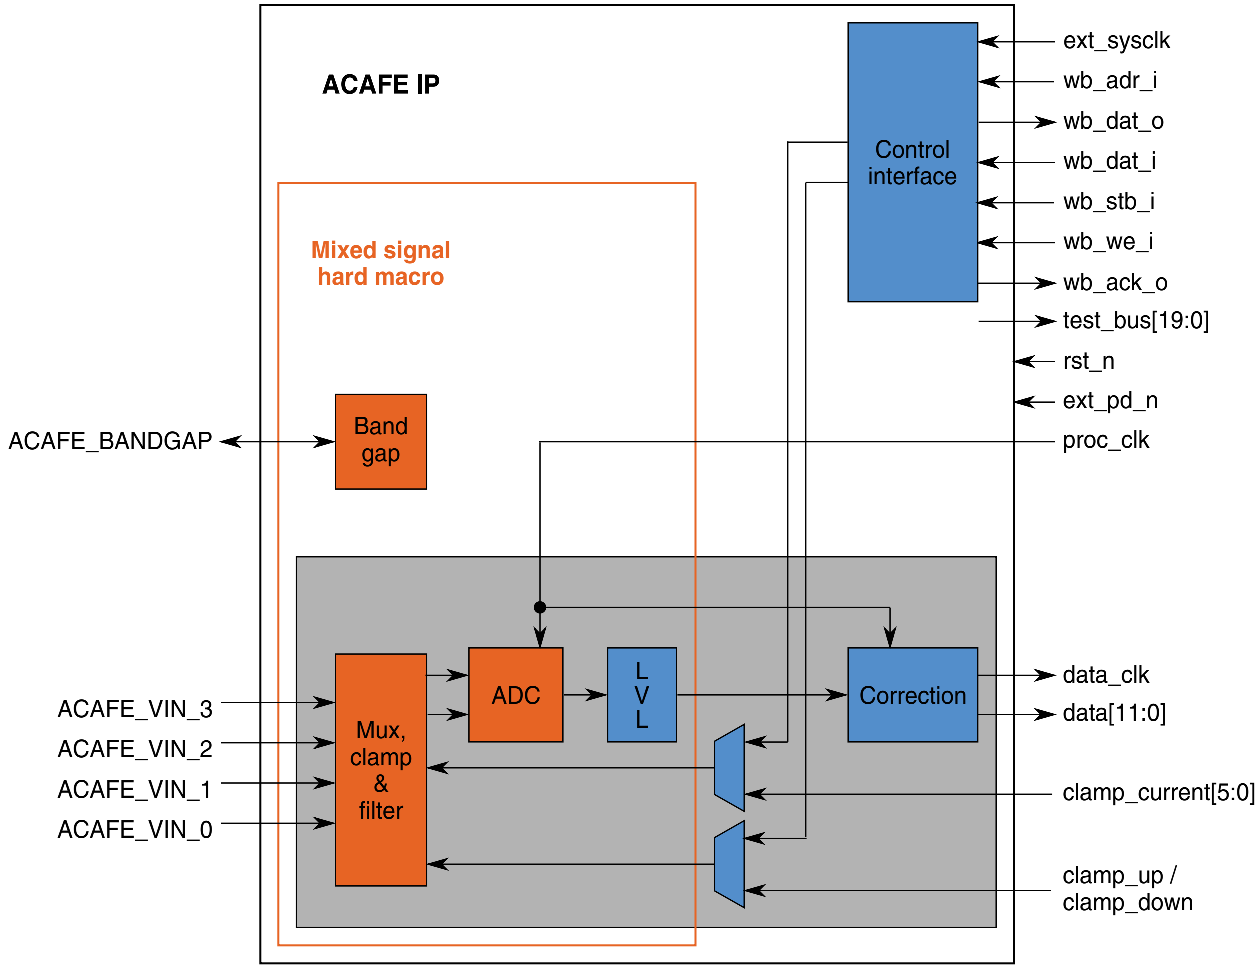

Figure 60-2. Analog front end block diagram

60.3.1 AFE features

The AFE includes the following features.

- Internal voltage and current reference generator
- 10-bit resolution (9.5 bit ENOB at 66.5 Msps)
- 30 mW at 66.5Msps power consumption
- 4 analog inputs. All inputs usable for CVBS.
- Programmable anti-aliasing filter, gain, and clamp

60.4 AFE memory map and registers

NOTE

The AFE registers must be programmed before enabling the Video ADC clock. Refer to the CCM_CSCDR1 register settings in the Clock Control Module chapter for more information.

60.5 Video decoder

The video decoder is comprised of the following blocks.

- DVB/ATSC demodulator
- NTSC/PAL IF demodulator
- NTSC/PAL decoder
- Video processing, noise reduction, de-interlacing, and scaling

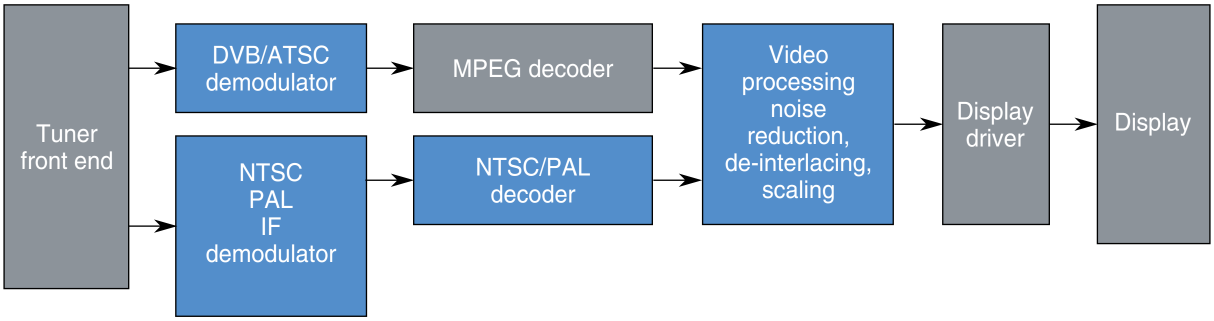

Figure 60-30. Video decoder block diagram

60.5.1 Video decoder features

The video decoder includes the following features.

- NTSC/PAL decoder
- Direct data path (no complex resampling)
- Automatic standards detection
- 2D adaptive comb filter
- Datapath/clocking architecture encompasses a time base corrector for VCR signals
- Luma passband is flat to >6MHz

60.6 Video decoder memory map and registers

VDEC_VSCON1 field descriptions

Field	Description
31–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 rh_8or16	Vsync detector

Table continues on the next page...

VDEC_VSCON1 field descriptions (continued)

Field	Description
	Select vsync detector 0 new 16 long vsync detector 1 old shorter vsync detector
6 rh_modadd_dis	Debug Debug test mode only
5 rh_ vsynchalfmode	Vsync half mode Use half lines instead of quarter lines.
4 rh_dis_ vsyncdetect	Disable vsync detection When set, do not look for any new vsync phases. Coast in previously found phase.
3 rh_robust625det	Robust 625 detection Selects a more robust method of determining 525 or 625 line mode. In particular this will coast in the last known mode in the event of no signal.
2–0 rh_vdet_dbg	Vsync debug mode Sets the Vsync debug output mode that can be seen by setting VIDOUTDBG[r_sel2] to 1. 0 Predicted location of Vsync 1 High when a new Vphase is set in the IP 2 Very simple Vsync detector for debug output only 3 High when several valid Vsyncs in a row are detected 4 High when this field's possible Vsync phases are looked at 5 The many detected Vsyncs (false and real) 6 High when twice as many Vsync phases are matching (i.e., twice as many as the 3 debug output). 7 Low-pass filtered luma falling edge detector. This is a crude Vsync detector used in conjunction with other methods to remove false detections

60.6.9 VSync Control 2 (VDEC_VSCON2)

Address: 400C_8000h base + 64h offset = 400C_8064h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Chapter 61
System JTAG Controller (SJC)

61.1 Introduction

System JTAG Controller (SJC) provides the security authentication for debug access to the chip. It is accessible through the JTAG Access Port (AP) of the ARM DAP.

This figure shows SJC connections to external contacts and other blocks.

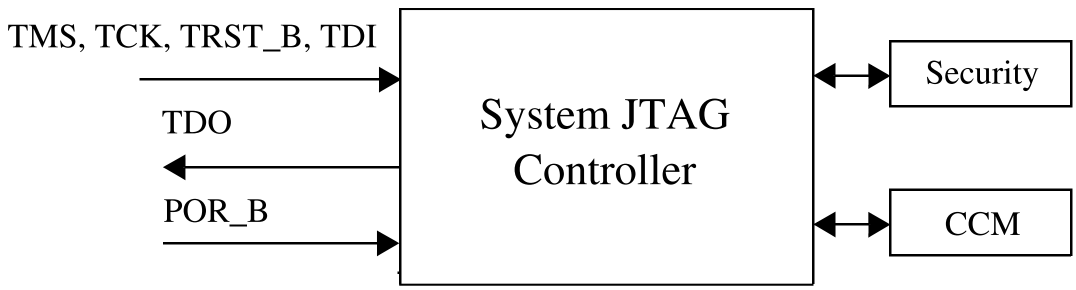

Figure 61-1. SJC connections

61.2 Programmable registers

This section lists additional registers to the standard accessible JTAG registers (per IEEE1149.1 standard). The following registers are accessed using the ExtraDebug mechanism, controlled by the ENABLE_ExtraDebug IR instruction.

NOTE

SJC registers are only accessible by JTAG interface and are not memory mapped to processor address space.

SJC memory map

Chapter 62
System Bus Interconnect

62.1 Overview

The CoreLink Network Interconnect (NIC301) is a second generation highly configurable IP component that enables the creation of a complete high performance, optimized AMBA-compliant network infrastructure. It is based around a high-performance AXI crossbar switch known as the AXI bus matrix.

Recall the AMBA-AXI protocol is ARM's Advanced e*X*ensible *I*nterface, the third generation AMBA interface definition. It is targeted for high performance, high frequency system designs and is suitable for high bandwidth, low latency data transfers. The key features of the AXI protocol include:

- Burst-based, split transaction bus
- Separate address/control and data phases
- Ability to issue multiple outstanding addresses
- Out-of-order transaction completion
- Five independent channels
    - Read address
    - Write address
    - Read data
    - Write data
    - Write response
- Each channel uses 2-way handshake mechanism (VALID, READY control signals)

The possible configurations for the CoreLink Network Interconnect can range from a single bridge component, for example an AHB to AXI protocol bridge, to a complex infrastructure that consists of up to 128 masters and 64 slaves of a combination of different AMBA protocols.

As the device includes a large number of bus master and slave devices implementing both AXI and AHB bus protocols with 32- or 64-bit datapath widths and operating at multiple synchronous frequencies, the NIC301 is an ideal system bus "fabric" and provides the needed hardware interconnect matrix for the device.

A CoreLink Network Interconnect configuration can consist of multiple switches with many topology options. Figure 62-1 shows a top-level block diagram of the CoreLink Network Interconnect that contains:

- Multiple switches
- Multiple AMBA Slave Interface Blocks (ASIBs)
- Multiple AMBA Master Interface Blocks (AMIBs)

Note in the context of the NIC301, a *system bus master* connects to an AMBA *Slave* Interface (ASIB) and a *bus slave* connects to an AMBA *Master* Interface Block (AMIB).

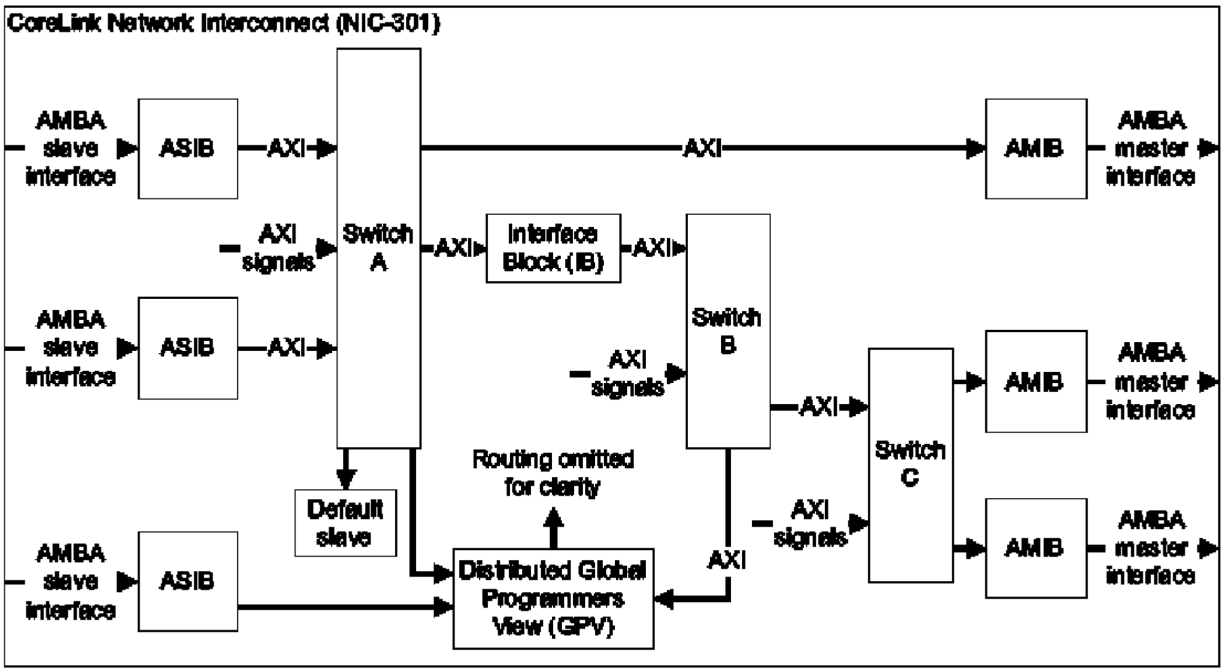

Figure 62-1. NIC301 Block Diagram

The table below provides an overview of the characteristics of the bus masters and slaves.

Table 62-1. Bus Master and Slave Interface Characteristics

Module	Type	interface Protocol	Interface Ports	Datapath Width	Operating Speed
Cortex-A5	Master	AXI	1	64b	High-speed Core
Cortex-M4	Master	AHB-Lite	2	64b	Low-speed Core = Platform
DMA2x	Master	AHB-Lite	2[1]	64b	Platform
DCU	Master	AXI	2[1]	64b	Platform
USB OTG	Master	AHB-Lite	2[1]	32b	Platform/2
Open VG	Master	AXI	1	64b	Platform
ENET	Master	AHB-Lite	2[2]	32b	Platform/2
VIU3	Master	AHB-Lite	1	64b	Platform
eSDHC	Master	AHB-Lite	2[1]	32b	Platform
NFC	Master	AHB-Lite	1	32b	Platform
CAAM	Master	AXI	1	32b	Platform
Debug Access Port (DAP)	Master	AHB-Lite	1	32b	Platform
ROM	Slave	AHB-Lite	1	64b	Platform
FlexBus	Slave	AHB-Lite	1	32b	Platform
QuadSPI, RLE	Slave	AHB-Lite	2[1]	64b	Platform
OCRAM	Slave	AXI	3[1]	64b	Platform
CM4_TCM	Slave	AHB-Lite	1	64b	Platform
SDRAMC (DDR)	Slave	AXI	2	64b	Platform
SecureRAM	Slave	AXI	1	32b	Platform
PBRIDGE (Peripheral Bridges)	Slave	AHB-Lite	2	64b	Platform

1. For these master and slaves, the multiple interface ports are due to multiple instances of the given module, for example, there are two DCU modules and two DMA2x modules. etc.
2. One of the ENET master ports (ENET1) is statically muxed with the master port from the MLB50 module which supports the MediaLB protocol for transfers on the MOST®data network. From the perspective of the NIC301 switch, the combined ENET1/MLB50 port appears as a single bus master.

62.2 Features

The CoreLink Network Interconnect NIC301 is a highly configurable infrastructure component that includes the following features:

- 1-128 AXI or AHB-Lite slave interfaces for bus master connections
- 1-64 master interfaces that can be AXI, AHB-Lite, APB2, or APB3 for bus slave connections
- Single-cycle arbitration Full pipelining to prevent master stalls
- Programmable control for FIFO transaction release

- Multiple switch networks
- AXI or AHB-Lite masters and slaves
    - Address width of 32-64 bits
    - Data width of 32, 64, 128, or 256 bits
- Non-contiguous APB slave address map for a single master interface
- Independent widths of user-defined sideband signals for each channel
- Global Programmers View (GPV) for the entire infrastructure, configurable for customizing the memory mapped visibility
- Highly flexible timing closure options

A very important attribute of the entire system bus fabric supported by the NIC301 and its split transaction protocol is the ***optimization for multi-master data bandwidth*** (versus data transfer latencies). *The device architecture implements a high performance microprocessor architecture where system performance is maximized by making effective use of the processor local memories (L1 and L2 caches, tightly coupled memories) and 32-byte cache line size 4-beat burst data transfers on the system bus fabric*. In environments and application spaces where these runtime characteristics are *not met*, data latency concerns can degrade system performance substantially.

62.3 NIC301 Physical Structure and Programming Model

62.3.1 NIC301 Physical Structure

The port assignments and NodeNumbers are of interest in the this section's discussion on the physical structure of the NIC301. The NodeNumbers are associated with the NIC301's Global Programmers View of the control and configuration registers. See Table 62-2

Table 62-2. NIC301 Port Assignments and NodeNumbers

Module	Type	PortNumber	NodeNumber
Cortex-M4 Code	Master	m0	66
Cortex-M4 System	Master	m1	67
Cortex-A5	Master	m2	68
DMA2x0	Master	m3	69
DMA2x1	Master	m4	70
DCU0	Master	m5	71
USB OTG0	Master	m6	72
Open VG	Master	m7	73

Table continues on the next page...

Table 62-2. NIC301 Port Assignments and NodeNumbers (continued)

Module	Type	PortNumber	NodeNumber
ENET0	Master	m8	74
ENET1 / MLB50	Master	m9(a,b)	75
VIU3	Master	m10	76
USB OTG1	Master	m11	77
DCU1	Master	m12	78
eSDHC0	Master	m13	79
eSDHC1	Master	m14	80
NFC	Master	m15	81
CAAM	Master	m16	82
Debug Access Port (DAP)	Master	m17	83
ROM	Slave	s0	2
FlexBus	Slave	s0	2
PBRIDGE0	Slave	s0	2
CM4_TCMx	Slave	s1	3
PBRIDGE1	Slave	s1	3
QuadSPI0	Slave	s2	4
OCRAM0_sys	Slave	s3	5
OCRAM1_sys	Slave	s4	6
OCRAM2_gfx	Slave	s5	7
SecureRAM	Slave	s6	8
QuadSPI1	Slave	s7	9
RLE	Slave	s7	9
SDRAMC (DDR0)	Slave	s8	10
SDRAMC (DDR1)	Slave	s9	11

NOTE

Masters that can access S8 (DDR0):

- M0, M1 (CM4)
- M5 (DCU0)
- M6 (USB)
- M10 (VIU2)
- M3, M8, M13, M15, M17 (DMA0, ENET0, eSDHC0, NFC, DBG)

NOTE

Masters that can access S9 (DDR1) are:

- M2 (CA5)
- M7 (Open VG)

- M12 (DCU1)
- M4, M9a, M9b, M11, M14, M16 (DMA1, ENET1, MLB, USB, eSDHC2, CAAM)

NOTE

There are a few restrictions on the masters that can access S6 port. The following masters cannot access S6 (SecureRAM):

- M5 (DCU0)
- M7 (Open VG)
- M10 (VIU2)
- M12 (DCU1)

Note the multiple shared NIC301 port connections (s0, s1, s7) to slave modules. For these shared slave connections, the device dual core platform includes “port splitters” to route the data transfers to the appropriate target module.

The internal structure of the device NIC301 implementation is shown in the figure below. For this complex system bus fabric, the structure balances the masters and slaves based on the expected data traffic and by grouping modules with similar bus protocols. The structure includes 3 master switch concentrators feeding, along with 6 masters with direct connections, into the main bus switch (switch3). Additionally, there is a 1-to-4 bus splitter on the slave side of the main switch. The resulting structure represents a trade-off balancing bus switch size, MHz timing and system bandwidth considerations.

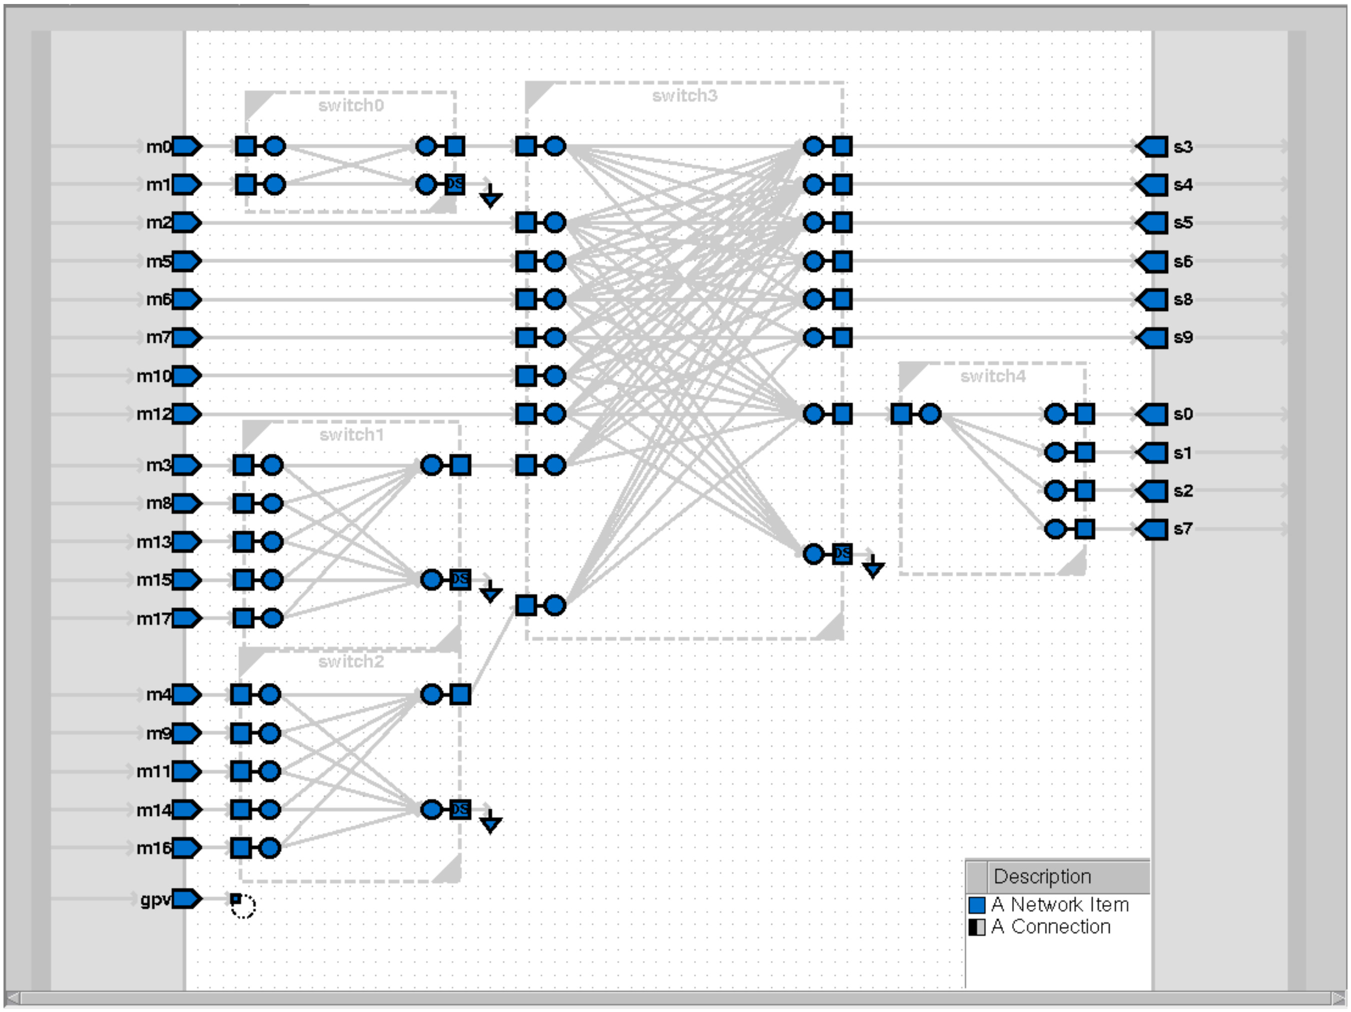

Figure 62-2. NIC301 Physical Block Diagram

62.3.2 NIC301 Programming Model

The individual AMBA master and slave interface blocks contained in the NIC301 each support a number of configuration registers for defining the operation of the bus switch. This section provides details on the memory map associated with the NIC301's GPV address space; details on the operation of specific control fields within these GPV registers can be found in the appropriate ARM documentation. The device implementation only allows privilege mode references; attempted references in user mode are error terminated.

As previously noted, the NIC301 is a very highly configurable IP component. To support the wide range of possible NIC301 configurations, the GPV is defined by the maximum configuration, and occupies a 1 Mbyte address space consisting of 256 4 Kbyte address spaces. Specifically, this 1 Mbyte address space consists of the following concatenation of register blocks:

- Address control register block
- Peripheral ID register block
- 64 master interface (AMIB) register blocks
- 128 slave interface (ASIB) register blocks
- 62 internal interface (IB) register blocks

Unfortunately, the replicated register blocks are *very sparsely populated*, both in terms of address locations used as well as the total number of defined register bits. As examples, the AMIB register block only includes 14 register bits per 4 Kbyte space; the ASIB includes 21 registers bit per 4 Kbyte space and the IB 12 register bits per 4 Kbyte space. The internal interface (IB) register blocks are *not used in the device*, but are partially supported in the architectural definition of the GPV address compression scheme.

The device uses an address compression technique to reduce the NIC301 GPV address space from 1 MB down to 32 Kbytes, which is then mapped to 8 consecutive 4 Kbyte "slots" managed by the PBRIDGE0 bus controller. This space is located at addresses 0x4000_8000 - 0x4000_FFFF in the device memory map.

To support the required 32:1 address space compression, the GPV's 20-bit 1 Mbyte address must be reduced to a 15-bit 32 Kbyte address for the PBRIDGE. For the GPV, the register base offset address is calculated as 4096 * NodeNumber; in general, the PBRIDGE register offset address is defined as 256 * NodeNumber with special handling of ADDR[7] providing the final bit of address compression. See Table 62-3 for the association between the GPV and PBRIDGE register address offsets. Recall the NodeNumbers were defined in Table 62-2

Table 62-3. NIC301 GPV → PBRIDGE Base Address Offset Compression

GPV Register Block	GPV Base Offset	PBRIDGE Base Offset	NodeNumber	GPV Address Offset	PBRIDGE Address Offset
Address Control	0x0_0000	0x0000	0	4096 * NodeNumber	256 * NodeNumber
Peripheral ID	0x0_1000	0x0100	1	4096 * NodeNumber	256 * NodeNumber

The final details associated with the GPV address space compression involves the behavior of ADDR[7]. For register offsets < 0x80, the GPV and PBRIDGE addresses are identical. Fortunately, the number of register offsets not meeting this condition are small in number. See Table 62-4 for the details on the required compression between GPV_ADDR[11:0] and PBRIDGE_ADDR[7:0].

Table 62-4. NIC301 GPV and PBRIDGE Register Offset Addresses

GPV Register Block	GPV_ADDR [11:0]	PBRIDGE_ADDR [7:0]	Register
All	< 0x080	< 0x80	Any register with these offsets
Address Control	0x080	0x80	security30
	0x084	0x84	security31 (Max GPV address = 0x084)

62.3.3 NIC301 Bus Arbitration

The NIC301 switch implements a two level arbitration mechanism that is partially programmable.

There is a 4-bit *Quality of Service (QoS)* priority that can be assigned (both a default value at reset plus a software programmed value) to each master port. Within the NIC301, the arbitration logic uses the QoS values for a first level fixed priority scheme; the higher the QoS value, the higher the master's priority. For multiple requesting masters with the same QoS value, a second level least-recently-used (also known as a least-recently-granted) scheme is applied.

The NIC301 Technical Reference Manual states “At any arbitration node, a fixed priority exists for transactions with a different QoS. The highest value has the highest priority. If there are coincident transactions at an arbitration node with the same QoS that require arbitration, then the Network uses a Least Recently Used (LRU) algorithm.”

Given these arbitration capabilities, the device dual-core platforms defines a default set of QoS values that represents a “recommended system configuration”. The default QoS values for the NIC301's bus masters are shown in Table 62-6

Table 62-6. NIC301 Default QoS Arbitration Priorities

System Bus Master	Port Number	Default QoS
Cortex-M4 Core	m0	1
Cortex-M4 System	m1	2
Cortex-A5	m2	0
DMA2x0	m3	4
DMA2x1	m4	4

Chapter 63
Miscellaneous Control Module (MCM)

63.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The Miscellaneous Control Module (MCM) provides a myriad of miscellaneous control functions.

63.1.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision

63.2 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

MCM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E008_0008	Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)	16	R	00FFh	63.2.1/3450
E008_000A	Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)	16	R	00FFh	63.2.2/3451
E008_000C	Control Register (MCM_CR)	32	R/W	0000_0000h	63.2.3/3452

Table continues on the next page...

MCM memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E008_0010	Interrupt Status and Control Register (MCM_ISCR)	32	R	0002_0000h	63.2.4/3453
E008_0020	Fault address register (MCM_FADR)	32	R	Undefined	63.2.5/3456
E008_0024	Fault attributes register (MCM_FATR)	32	R	Undefined	63.2.6/3457
E008_0028	Fault data register (MCM_FDR)	32	R	Undefined	63.2.7/3459

63.2.1 Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)

PLASC is a 16-bit read-only register identifying the presence/absence of bus slave connections to the device's crossbar switch.

Address: E008_0000h base + 8h offset = E008_0008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ASC							
Write																
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

MCM_PLASC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–0 ASC	Each bit in the ASC field indicates whether there is a corresponding connection to the crossbar switch's slave input port. 0 A bus slave connection to AXBS input port *n* is absent 1 A bus slave connection to AXBS input port *n* is present

63.2.2 Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)

PLAMC is a 16-bit read-only register identifying the presence/absence of bus master connections to the device's crossbar switch.

Address: E008_0000h base + Ah offset = E008_000Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								AMC							
Write																
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

MCM_PLAMC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–0 AMC	Each bit in the AMC field indicates whether there is a corresponding connection to the AXBS master input port. 0 A bus master connection to AXBS input port *n* is absent 1 A bus master connection to AXBS input port *n* is present

63.2.3 Control Register (MCM_CR)

CR defines the arbitration and protection schemes for the two system RAM arrays.

Address: E008_0000h base + Ch offset = E008_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	SRAMLWP	SRAMLAP		0	SRAMUWP	SRAMUAP		Reserved							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved						Reserved	Reserved								
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MCM_CR field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 SRAMLWP	SRAM_L Write Protect When this bit is set, writes to SRAM_L array generates a bus error.
29–28 SRAMLAP	SRAM_L arbitration priority Defines the arbitration scheme and priority for the processor and SRAM backdoor accesses to the SRAM_L array. 00 Round robin 01 Special round robin (favors SRAM backoor accesses over the processor) 10 Fixed priority. Processor has highest, backdoor has lowest 11 Fixed priority. Backdoor has highest, processor has lowest
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MCM_CR field descriptions (continued)

Field	Description
26 SRAMUWP	SRAM_U write protect When this bit is set, writes to SRAM_U array generates a bus error.
25–24 SRAMUAP	SRAM_U arbitration priority Defines the arbitration scheme and priority for the processor and SRAM backdoor accesses to the SRAM_U array. 00 Round robin 01 Special round robin (favors SRAM backoor accesses over the processor) 10 Fixed priority. Processor has highest, backdoor has lowest 11 Fixed priority. Backdoor has highest, processor has lowest
23–10 Reserved	This field is reserved.
9 Reserved	This field is reserved.
8–0 Reserved	This field is reserved.

63.2.4 Interrupt Status and Control Register (MCM_ISCR)

The MCM_ISCR register defines the configuration and reports status for a number of core-related interrupt exception conditions. It includes the enable and status bits associated with the core's floating-point exceptions, bus errors associated with the core's cache write buffer, and events associated with the debug ETB module. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these bits are ignored. Once set, the flags remain asserted until software clears the corresponding FPSCR bit.

Address: E008_0000h base + 10h offset = E008_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	FIDCE	0		FIXCE	FUFCE	FOFCE	FDZCE	FIOCE	0			CWBEE	Reserved

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FIDC	0		FIXC	FUFC	FOFC	FDZC	FIOC	0			CWBER	DHREQ	0		
W												w1c				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MCM_ISCR field descriptions

Field	Description
31 FIDCE	FPU input denormal interrupt enable 0 Disable interrupt 1 Enable interrupt
30–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 FIXCE	FPU inexact interrupt enable 0 Disable interrupt 1 Enable interrupt
27 FUFCE	FPU underflow interrupt enable 0 Disable interrupt 1 Enable interrupt
26 FOFCE	FPU overflow interrupt enable 0 Disable interrupt 1 Enable interrupt
25 FDZCE	FPU divide-by-zero interrupt enable 0 Disable interrupt 1 Enable interrupt
24 FIOCE	FPU invalid operation interrupt enable 0 Disable interrupt 1 Enable interrupt
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 CWBEE	Cache write buffer error enable Enables the generation of an interrupt in response to a bus error termination reported on a system bus transfer initiated from the cache's write buffer.

Table continues on the next page...

MCM_ISCR field descriptions (continued)

Field	Description
	0 Disable error interrupt 1 Enable error interrupt
19–16 Reserved	This field is reserved.
15 FIDC	FPU input denormal interrupt status This read-only bit is a copy of the core's FPSCR[IDC] bit and signals input denormalized number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IDC] bit. 0 No interrupt 1 Interrupt occurred
14–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 FIXC	FPU inexact interrupt status This read-only bit is a copy of the core's FPSCR[IXC] bit and signals an inexact number has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IXC] bit. 0 No interrupt 1 Interrupt occurred
11 FUFC	FPU underflow interrupt status This read-only bit is a copy of the core's FPSCR[UFC] bit and signals an underflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[UFC] bit. 0 No interrupt 1 Interrupt occurred
10 FOFC	FPU overflow interrupt status This read-only bit is a copy of the core's FPSCR[OFC] bit and signals an overflow has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[OFC] bit. 0 No interrupt 1 Interrupt occurred
9 FDZC	FPU divide-by-zero interrupt status This read-only bit is a copy of the core's FPSCR[DZC] bit and signals a divide by zero has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[DZC] bit. 0 No interrupt 1 Interrupt occurred
8 FIOC	FPU invalid operation interrupt status This read-only bit is a copy of the core's FPSCR[IOC] bit and signals an illegal operation has been detected in the processor's FPU. Once set, this bit remains set until software clears the FPSCR[IOC] bit. 0 No interrupt 1 Interrupt occurred
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MCM_ISCR field descriptions (continued)

Field	Description
4 CWBER	Cache write buffer error status Signals a data transfer from the core's cache write buffer was terminated with a bus error. This bit only sets when the corresponding enable bit (CWBEE) is set. The corresponding core fault address, attributes and write data are typically retrieved from the FADR, FATR, and FDR registers during the interrupt service routine before clearing the CWBER flag. 0 No error 1 Error occurred
3 DHREQ	Debug Halt Request Indicator Indicates that a debug halt request is initiated due to a ETB counter expiration, ETBCC[2:0] = 3b111 & ETBCV[10:0] = 11h0. This bit is cleared when the counter is disabled or when the ETB counter is reloaded. 0 No debug halt request 1 Debug halt request initiated
2–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

63.2.5 Fault address register (MCM_FADR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting address is captured in the MCM_FADR register. The MCM logic supports capturing a single cache write buffer bus error event; if a subsequent error is detected before the captured error information has been read from the corresponding registers and the MCM_ISCR[CWBER] indicator cleared, the MCM_FATR[BEOVR] flag is set. However, no additional information is captured.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 20h offset = E008_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- x = Undefined at reset.

MCM_FADR field descriptions

Field	Description
31–0 ADDRESS	Fault address

63.2.6 Fault attributes register (MCM_FATR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting attributes are captured in the MCM_FATR register.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 24h offset = E008_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

* Notes:
- x = Undefined at reset.

MCM_FATR field descriptions

Field	Description
31 BEOVR	Bus error overrun Indicates if anothercache write buffer bus error is detected before system software has retrieved all the error information from the original event, this overrun flag is set. The window of time is defined from the detection of the original cache write buffer error termination until the MCM_ISCR[CWBER] is written with a 1 to clear it and rearm the capture logic. This bit is set by the hardware and cleared whenever software writes a 1 to the CWBER bit. 0 No bus error overrun 1 Bus error overrun occurred. The FADR and FDR registers and the other FATR bits are not updated to reflect this new bus error.
30–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 BEMN	Bus error master number Crossbar switch bus master number of the captured cache write buffer bus error. For this device, this value is always 0x1.
7 BEWT	Bus error write Indicates the type of system bus access when the error was detected. Since this logic is monitoring data transfers from the cache write buffer, this bit is always a logical one, signaling a write operation. 0 Read access 1 Write access
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 BESZ	Bus error size Indicates the size of the cache write buffer access when the error was detected. 00 8-bit access 01 16-bit access 10 32-bit access 11 Reserved
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BEMD	Bus error privilege level Indicates the privilege level of the cache write buffer access when the error was detected. 0 User mode 1 Supervisor/privileged mode
0 BEDA	Bus error access type Indicates the type of cache write buffer access when the error was detected. This attribute is always a logical one signaling a data reference. 0 Instruction 1 Data

63.2.7 Fault data register (MCM_FDR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting data is captured in the MCM_FDR register.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. For byte and halfword writes, only the accessed byte lanes contain valid data; the contents of the other bytes are undefined. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 28h offset = E008_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 64 AHB-TrustZone Address Space Controller (AHB-TZASC)

64.1 Overview

The AHB-TZASC provides functionality equivalent to the (AXI) TZASC module. There are four instances of the basic AHB-TZASC functionality, each supporting 8 memory "region descriptors" with a programming model exactly equivalent to the (AXI) TZASC's capabilities.

64.2 Memory Map and Register Descriptions

This section provides an overview summary of the AHB-TZASC's programming model. See the (AXI) TZASC documentation for the specific register details. In particular, see the ARM technical reference manual, *DDI0431C_tzasc_tzc380_r0p1_trm.pdf*.

Each instance of the AHB-TZASC is allocated a 1 KB address space, so that all 4 instances can be supported in a single 4 KB slave peripheral slot (on-platform slot 16, based at address 0x4001_0000) of the PBRIDGE0 controller.

Table 64-1. AHB-TZASC Programming Model Memory Map

System Base Address Range	AHB-TZASC Programming Model Description
0x4001_0000 - 0x4001_03FF	FlexBus
0x4001_0400 - 0x4001_07FF	CM4's Tightly-Coupled Memory Backdoor Port
0x4001_0800 - 0x4001_0BFF	QuadSPI0
0x4001_0C00 - 0x4001_0FFF	QuadSPI1

The programming model for *each* instance is shown in Table 64-2.

Table 64-2. AHB-TZASC Programming Model Map Details

64.2.0.1 AHB-TZASC Programming Model Differences vs. (AXI) TZASC

The (AXI) TZASC module supports the notion of read and write speculative accesses. This support reflects, to some degree, to the basic nature and timing requirements of the AXI protocol. At reset, both read and write speculations are enabled and the transaction address and attributes are forwarded to the slave destination *before* the validity of the access has been evaluated.

The TZASC allows AXI data transfers only if the access check allows the reference; if the access check detects a violation, the data transfer is inhibited and the access is redefined as a Denied AXI transaction.

The address speculation is programmable and can be disabled by asserting the appropriate bits in the speculation_control register. There are system performance implications: if address speculation is disabled, then the *TZASC module adds one clock cycle of latency to perform the access check before the address is forwarded* to the slave destination.

By contrast, the *AHB-TZASC does not support, nor need any form of address speculation*. Instead, the module is able to perform the required access check on-the-fly without adding any cycle of latency. If the access check indicates a violation, the AHB-TZASC module is still able to inhibit the reference to the slave.

Accordingly, there are 3 register bits in the TZASC programming model that are specifically related to the address speculation and *not implemented* in the AHB-TZASC module. As highlighted in Figure 64-1, these include:

1) Register bit = lockdown_select[2]

This register bits provides a lock function for speculation_control register, making its content read-only. Since the AHB-TZASC module does not need nor support speculation, this bit is not required and therefore not implemented. This bit is RAZ/WI.

2) Register bits = speculation_control[1:0]

These register bits control the read and write address speculation. Again, since the AHB-TZASC module does not need nor support speculation, these bits are not required and not implemented. These bits are RAO/WI (read as one, write ignored). This signals that speculation is disabled, but as discussed previously, there are *no added cycles of latency.*

In addition to these programming model differences, the AHB-TZASC does *not* implement the integration test registers (itop, itip, itcrg) nor the component configuration registers (periph_id_[4:0], component_id[3:0]).

Chapter 65 On-Chip Memory Controllers

65.1 Overview

The device includes an on-chip ROM (OCROM) controller supporting an 8 MB address space plus three on-chip RAM (OCRAM) memory controllers also supporting an 8 MB address space allocated for this storage type.

The OCRAM address space is logically partitioned into two equal 4 MB spaces: one defined for system RAM (sys) and the other for graphics RAM (gfx). The Faraday architecture spreads 1.5 MB of RAM across three controllers to provide an appropriate amount of data bandwidth to this critical system memory. Additionally, the capabilities associated with these memories vary, based on the required functionality. See Table 65-1 for details.

Table 65-1. On-Chip Map Region Details

Start Address	End Address	Size [Kbytes]	OCMEM Description	Features
On-chip ROM				
0x0000_0000	0x007F_FFFF	8192	OCROM(3)	Boot Memory
On-chip RAM				
0x3F00_0000	0x3F03_FFFF	256	OCRAM0_sys	ECC protected
0x3F04_0000	0x3F07_FFFF	256	OCRAM1_sys	ECC protected
0x3F08_0000	0x3F3F_FFFF	3584	Reserved for Future Use	
0x3F40_0000	0x3F47_FFFF	512	OCRAM2_gfx	Pixel Converter
0x3F48_0000	0x3F4F_FFFF	512	*Configurable* OCRAM2 gfxRAM or, Data Array for L2 Cache	Pixel Converter
0x3F50_0000	0x3F7F_FFFF	3072	Reserved for Future Use	

Each OCRAM*n* controller is a 64-bit AXI implementation, optimized for maximizing data bandwidth with a *3-stage pipelined single-cycle memory structure*. The pipeline stages include: (1) address/write data setup, (2) RAM array access, and (3) read data return. The first pipeline stage overlaps with the last stage of the NIC301 data pipeline.

The remainder of this section provides details on the error correcting code (ECC) associated with the OCRAM_sys memory, the pixel converter associated with the OCRAM_gfx memory and the programming model.

65.1.1 OCRAM_sys Error Correcting Code (ECC)

To support market requirements related to improved functional and transient fault detection capabilities, this device includes ECC support on the system memory portion of the on-chip RAM. This implementation follows the traditional memory ECC design as the check logic is localized to the OCRAM_sys memory controllers.

The implemented ECC is a single error correction, double error detection (SECDED) code using a Hsiao minimum odd weight column definition. The ECC is calculated based on a 64-bit data width. Additionally, the error codes are generated based on more than just the data associated with the storage location in order to protect additional information associated with an access. Specifically, the address corresponding to the access location is combined with the data in the OCRAM_sys controllers to generate error protection codes which cover certain types of addressing errors which may occur in the memory controller or memory array(s). The *8-bit ECC implementation in the OCRAM_sys memory controllers cover the 64 data bits plus the upper 29 bits of the access address*. Details on the H matrix which defines the relationship between the 29-bit address and the 64-bit data fields to produce the 8 checkbits are provided in Section 65.1.1.1, “ECC Checkbit/Syndrome Coding Details”. Note that only single bit errors in the data or checkbit fields can be corrected (on-the-fly); single bit errors pointing to the address field and all detected multi-bit errors are treated as uncorrectable ECC events. Note the terminology uncorrectable or non-correctable are used interchangeably.

The OCRAM_sys ECC function can be summarized in the following steps. Consider reads and writes separately.

For data writes received by the OCRAM_sys memory controller:

- If enabled, the ECC logic generates the 8-bit checkbit field based on the 29-bit address + 64-bit data
- The 64 data bits + 8 checkbits are stored in the memory

For data reads processed by the OCRAM_sys memory controller:

- The memory reads the addressed location returning 64 data bits + 8 checkbits
- If enabled, the ECC logic forms an 8-bit syndrome which is the XOR of the 8 checkbits read from memory and the (re)calculated checkbits formed by passing the 64 data bits (plus the address field checkbits) through the H-matrix logic. An all-zero syndrome indicates an error-free memory read, else a memory corruption event has occurred.
- The ECC logic decodes the syndrome to determine if the event is a 1-bit data error that can be corrected on the fly, or some type of uncorrectable (aka non-correctable) ECC event. If the data or checkbits contains a 1-bit error, it is corrected and returned to the requesting bus master; The device optionally includes the ability to generate an ECC alert interrupt signaling a correctable 1-bit data error occurred. For uncorrectable ECC events, the bus transfer is terminated with an error response, and a separate ECC alert interrupt can be generated. Additionally, the Miscellaneous System Control Module (MSCM) module contains hardware to record the specifics of the uncorrectable ECC event. The Section XREF HERE for details.

Recall the ECC is organized based on a 64-bit data field. Accordingly, the OCRAM_sys memory controllers automatically performs the *required read-modify-write* sequence needed to generate the correct 8 checkbits when a memory write of less than 64 bits is performed. Consider an 8-bit byte write; for this operation, the OCRAM_sys controller reads the 64-bit data location containing the byte to be updated, performs the standard data read ECC evaluation (correcting any single-bit errors) and then merges the new data byte into the 64-bit read data, calculates the new checkbits and writes the entire 64 data bits and 8 checkbits back into the memory. If the read portion of this sequence detects an uncorrectable ECC event, it is immediately signaled, the data write error terminated and the memory update aborted.

The ECC read-modify-write adds two cycles of latency on a less-than-64 bit write: one cycle is needed for the read and a second cycle to perform the ECC operations associated with the read syndrome generation and possible on-the fly correction. The new data is merged with the read data in the “normal” write setup cycle. *Given this 2 cycle latency addition for ECC read-modify-writes, for maximum system performance, writes less than 64 bits should be minimized and/or operated in a decoupled (aka “imprecise”) manner to lessen their impact.*

Note standard ECC operation requires that the entire memory be written during system startup to “initialize” correct checkbit values for all locations before read operations can be checked. To assist in this process, the device implements two independent control flags for each OCRAM_sys controller: one that enables checkbit generation on writes and another to enable checking on read operations. The memory initialization writes can be performed directly by a processor or an appropriately configured DMA channel.

65.1.1.1 ECC Checkbit/Syndrome Coding Details

In the device, ECC scheme implements a single-error correction, double-error detection code using the so-called Hsiao minimum odd-weight column criteria. The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting specification of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is “odd weight”.

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. The resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of “data” bits (64 data + 29 address), 101 is the total number of data and address bits plus 8 checkbits) is shown in Table 65-10, where an ‘*’ indicates the corresponding data or address bit is XOR’ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR’ed) together to the final value driven on the checkbit[7:0] outputs.

0	*		*	*	*			*	*		*		*	*	*		*		*	*	*			*		*	*		*			

1 Bit numbering follows the standard ARM-AMBA little endian convention with bit 0 as LSB: D[7:0] corresponds to byte at address 0, and D[63:56] corresponds to byte at address 7.

Figure 65-1 shows an alternative representation of the ECC encode process, written as a C language function.

Figure 65-1. C Language encodeECC Function Description

```
encodeEcc (addr, data64)
    unsigned int        addr;                          /* 32-bit byte address */
    unsigned long long  data64;                        /* 64-bit data */

{
    unsigned int        addr_ecc;                      /* 8 bits of ecc for address */
    unsigned int        ecc;                           /* 8 bits of ecc codeword */

    /* the following equations calculates the 8-bit wide ecc codeword by examining
    each addr or data bit and xor'ing the appropriate H-matrix value if the bit = 1 */

    addr_ecc
        = (((addr   >> 31) & 1) ? 0x1f : 0x0)      /* addr[31] */
        ^ (((addr   >> 30) & 1) ? 0xf4 : 0x0)      /* addr[30] */
        ^ (((addr   >> 29) & 1) ? 0x3b : 0x0)      /* addr[29] */

    ecc = ecc ^ addr_ecc;   /* combine data and addr ecc values */
    return(ecc);
}
```

As the ECC syndrome is calculated on a read operation by applying the H-matrix to the data plus the checkbits, an all zero syndrome indicates an error free operation. *If the generated syndrome value is non-zero and matches one of the H-matrix values associated with the data or checkbits, it represents a single-bit error correction case and the specific bit is complemented to produce the correct data value*. If the syndrome value matches one of the H-matrix values associated with the address bits, or is an even weight value, or represents an unused odd weight value, a non-correctable ECC event has been detected and the appropriate error termination response is initiated.

Details on the MSCM programming model registers associated with ECC functionality are provided in Section XREF-HERE. This includes capabilities to insert errors to “check the checkers”, both the hardware as well as associated software routines, as well as logic to record bus cycle information at the time of an ECC event.

65.1.1.2 ECC and System Performance Implications

The logic used for the generation of checkbits on writes, calculation of the syndrome and on-the-fly single bit correction on reads is fundamentally integrated into the OCRAM memory controller’s microarchitecture. As a result, the enabling of ECC *does **not** add any machine cycles to RAM reads and 64-bit writes*.

As previously discussed, writes for sizes less than 64 bits require an additional 2 cycles of processing to perform the required read-modify-write to calculate the checkbits needed by the 64-bit ECC algorithm. Additionally, the enabling of the ECC check function requires that the appropriate memory has been completely written to place initialized data in all locations.

65.1.2 OCRAM_gfx Pixel Conversion

The performance of graphic algorithms on a SIMD extension like ARM NEON depends pretty much on the capability to efficiently load and store pixels in the appropriate format. The color components have to be placed in the components of the SIMD register to allow efficient processing.

For byte-aligned pixel format like ARGB8888 this can be easily achieved with the VLD and VST instructions of ARM NEON. While this pixel format offers the full color resolution it requires a significant amount of memory (32 bits per pixel). For single chip solutions without external memory this makes it difficult or even impossible to support larger displays.

One potential solution for this problem is to limit the color depth and spend only 16 bits per pixel for some or all frame buffers / layers. While this halves the amount of memory required for the frame buffers or

layers it is not well suited to be handled with ARM NEON as it requires significant pre-/post-processing to get the pixel components adjusted into the vector components of the SIMD registers.

While implementing the pixel packing and unpacking is a pretty performance intensive task on ARM NEON this is something that can be very easily implemented in a small hardware block located in the memory controller of the on-chip SRAM pool. The purpose of the Pixel Converter is to do the required conversions in a rather simple hardware block."

Accordingly, the Faraday memory controllers include a programmable ability to perform specific pixel conversions based on alternate address spaces mapped to the physical OCRAM_gfx memory. Specifically, the pixel converter hardware reformats memory-resident 16 bit graphics pixel data into 32 bit processor words for the Cortex-A5's NEON SIMD execution.

Graphics algorithms often require simultaneous support for three remapped regions as it is common to have images in two different formats blended together to create a third (output) image. Additionally, the core views the pixel data as "expanded" 32 bit words which is *double the size* of the actual packed 16 bit pixel data in the OCRAM_gfx.

Given the physical OCRAM_gfx space is defined as 4 MB, then the alternate pixel converter view needs 3 regions * (2 * 4 MB/region) = 24 MB as a minimum size. Rounding up, the Faraday memory map allocates 32 MB to this alternate pixel view into the OCRAM_gfx. This alternate pixel view is located in the system address space defined as 0x7E00_0000 - 0x7FFF_FFFF.

65.1.2.1 OCRAM_gfx Pixel Converter Functional Description

The three alternate OCRAM_gfx address spaces are dedicated to specific 16-bit pixel formats. The device architecture supports 3 formats, generically represented as {A}RGB{w}xyz where w defines the number of optional alpha bits, x is the number of red bits, y is the number of green bits and z is the number of blue bits:

- RGB565
- ARGB1555
- ARGB4444

Next, consider the actual data manipulations performed to convert these three 16-bit pixel formats into the 32-bit ARBG8888 format needed by the CA5's NEON SIMD engine. The required conversions are presented both graphically and in C code.

65.1.2.1.1 RGB565

In general, the pixel expansion process involves copying the {x,y,z} bits of the color component into the 8-bit ARGB8888 format left justified and then padding the remaining low-order bits with the appropriate number of most significant bits. The figure below shows the RGB565 conversion into ARGB8888. Throughout this section, let rx {x = 0, 1, 2, 3, 4} define the bits of the red color component, gy {y = 0, 1,

2, 3, 4, 5} be the bits of the green color component and bz {z = 0, 1, 2, 3, 4} the bits of the blue color component.

Figure 65-2. RGB565 → ARGB8888 Conversion

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
r0	r1	r2	r3	r4	g0	g1	g2	g3	g4	g5	b0	b1	b2	b3	b4

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	r0	r1	r2	r3	r4	r0	r1	r2	g0	g1	g2	g3	g4	g5	g0	g1	b0	b1	b2	b3	b4	b0	b1	b2

For this conversion, all 8 bits of the alpha byte are set in the AGRB8888 format (0xFF).

65.1.2.1.2 ARGB1555

Using the same notation, the ARGB1555 conversion into ARGB8888 is shown in below.

Figure 65-3. ARGB1555 → ARGB8888 Conversion

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
a0	r0	r1	r2	r3	r4	g0	g1	g2	g3	g4	b0	b1	b2	b3	b4

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
a0	a0	a0	a0	a0	a0	a0	a0	r0	r1	r2	r3	r4	r0	r1	r2	g0	g1	g2	g3	g4	g0	g1	g2	b0	b1	b2	b3	b4	b0	b1	b2

For this conversion, 1 bit alpha value is slewed across the upper byte of the AGRB8888 format.

65.1.2.1.3 ARGB4444

Using the same notation, the ARGB4444 conversion into ARGB8888 is shown in below.

Figure 65-4. ARGB4444 → ARGB8888 Conversion

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
a0	a1	a2	a3	r0	r1	r2	r3	g0	g1	g2	g3	b0	b1	b2	b3

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
a0	a1	a2	a3	a0	a1	a2	a3	r0	r1	r2	r3	r0	r1	r2	r3	g0	g1	g2	g3	g0	g1	g2	g3	b0	b1	b2	b3	b0	b1	b2	b3

65.1.2.1.4 ARGB8888 Conversions to 16-bit Pixel Data

The preceding sections provided details on the bit remapping when converting from the supported 16-bit pixel formats into the 32-bit ARGB8888 format. These conversions are performed on alternate address space *reads* of the OCRAM_gfx memory.

When performing a *write* of 32-bit ARGB8888 pixel data, the conversion process supports two modes of operation, uniquely selectable for each alternate pixel address space. The store modes are *truncation* or *round/clip*.

Truncation simply places the most significant bits for each color component into the available positions in the 16-bit target format.

Figure 65-5. ARGB8888 → ARGB4444 Conversion

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
a0	a1	a2	a3	a4	a5	a6	a7	r0	r1	r2	r3	r4	r5	r6	r7	g0	g1	g2	g3	g4	g5	g6	g7	b0	b1	b2	b3	b4	b5	b6	b7

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
a0	a1	a2	a3	r0	r1	r2	r3	g0	g1	g2	g3	b0	b1	b2	b3

For the truncation operation for this destination format, the low-order 4 bits of each color component, namely a[4-7], r[4-7], g[4-7] and b[4-7] are simply discarded when creating the 16-bit ARGB4444 format.

If the round/clip mode is enabled, the pixel converter first performs two's complement rounding (always round up) by adding a "1" to *the bit immediately to the right of the rounding point*. The rounding bit position is determined by the number of available bits in the given color component of the 16-bit data format; after the addition, the low-order bits to the right of the rounding point are discarded. Specifically, the rounding "1" factor is defined in a C language expression as `1 << (8 - bitwidth - 1)` where `bitwidth` is the size of the color component in the 16-bit pixel data.

After the rounding addition is performed, the result is checked for a carry out. If a carry out is signaled, the data has "overflowed" and the final color component is forced to all ones (the clipped value).

A complete definition of the round/clip functionality, is expressed in the following C code function.

Figure 65-6. Pixel Conversion C Code: Round/Clip Function

```
unsigned char roundclip (unsigned char intensity, int bitwidth)
{
    unsigned int val = intensity;
    val += 1U << (8-bitwidth-1);    /* rounding step */
    if (val & 0x100)                /* check for a cout */
        val = 0xff;                 /* set to clipped value*/

    return (val & 0xff);
}
```

where `intensity` is the source data byte extracted from the ARGB8888 format, and `bitwidth` is the number of bits available in the destination field of the 16-bit pixel data.

From the resulting value only the bitwidth MSBs are used, that is, a truncation step is applied after round/clip arithmetic is calculated.

65.1.2.2 Pixel Conversion and System Performance Implications

Like the ECC implementation, the pixel converter logic is fundamentally integrated into the OCRAM memory controller microarchitecture. As a result, the accesses via the pixel converters *do **not** add any machine cycles to 32- and 64-bit RAM reads and writes*. The conversion on writes is integrated into the first stage (address/write data setup) of the OCRAM's data pipeline and read conversions are handled in the third stage (read data return).

Chapter 66 Miscellaneous System Control Module (MSCM)

66.1 Introduction

The Miscellaneous System Control Module (MSCM) contains Access Control and TrustZone Security hardware, CPU Configuration registers and Interrupt Router control.

66.2 MSCM Access Control and TrustZone Security Memory Map and Register Descriptions

The memory-mapped registers that supports the access control and TrustZone security functions are distributed across multiple modules. In particular, the CSU and all instances of the TZASC controllers are involved along with a portion of the MSCM module. The pertinent MSCM programming model can only be accessed with privileged mode 32-bit references; any other access type or size are terminated with an error.

The MSCM memory map occupies a single 4 KB slave peripheral address space, based at system address 0x4000_1000. The access control and TrustZone security (ACTZS) portion of the MSCM memory map is allocated the upper quarter of the address space and is based at address 0x4000_1C00.

66.2.1 MSCM Access Control and TrustZone Security (ACTZS) Memory Map

The ACTZS configuration portion of the MSCM programming model map is shown in Table 66-1. It is partitioned into two sections:

- Offset addresses 0xC00 - 0xC18 define basic system control and configuration for all the TZASC modules and the CSU.
- Offset addresses 0xD00 - 0xDDC contain captured access address and attribute information for CSL-detected violations. For the logic evaluating the CSLn security levels for all the slave peripheral modules, the *errors are logically combined into one set of reporting registers for each PBRIDGE controller.*

Note, each TZASC module includes local registers within its programming model to record comparable information on TrustZone security violations.

Attempted writes to read-only registers are simply ignored (RO/WI). Privileged mode accesses of the reserved locations at offset addresses 0xC08 - 0xC0C and 0xC1C - 0xCFC are treated as RAZ/WI (read as zero, write ignored). Likewise, privileged mode accesses of the reserved locations at offset addresses 0xD04 + 16*n (n = 0-13) and 0xDE0 - 0xFFC are treated as RAZ/WI (read as zero, write ignored). Attempted user mode accesses in the ACTZS section (offset addresses 0xC00 - 0xDFC) are terminated with an error as are any references with a size smaller than 32 bits.

Table 66-1. MSCM ACTZS Configuration Memory Map

66.2.1.1 MSCM Access Control and TrustZone Security Register Descriptions

This section of the MSCM programming model includes a number of registers controlling the individual TrustZone checkers plus CSLn attribute check logic plus an array of 128-bit register structures containing captured CSLn fault information.

For all the ACTZS registers, privileged 32-bit reads from the CA5, the CM4 or the debugger return the appropriate register information. Reads from any other bus master return all zeroes (RAZ). Privileged writes from the CA5, CM4 or the debugger to writeable registers update the appropriate fields, while privileged writes from other bus masters are ignored (WI). Attempted user mode accesses or any access with a size different than 32 bits are terminated with an error.

66.2.1.1.1 ACTZS TrustZone Enable Register (MSCM_TZENR)

The TrustZone Enable Register is a 32-bit register containing a bit map of enables for each TrustZone Address Space Controller in the device.

Given the AXI-TZASC functionality is complex and can add a cycle of latency to accesses being checked, this register provides the mechanism to completely bypass the module if it is disabled. The register also contains a global TZASC control signal indicating a secure boot process completed and certain registers within the TZASC modules are locked and cannot be altered.

In addition to the TZENR register bits, there is a single device fuse bit that provides a further level of qualification. This fuse signal is combined with the individual TZENi bits to form the fully qualified TZASC enable for each instance:

```
qualified_TZENi =  MSCM_TZENR[i] &  tzenb_fuse
```

where `tzenb_fuse` serves as a global enable qualifier.

For the AHB-TZASC modules, the access checking is performed on-the-fly during the address phase bus cycle. If a given AHB-TZASC module is logically disabled, the internal logic is inhibited as if the `action[reaction_value]` register field is cleared meaning neither bus error terminations nor security violation interrupts are generated.

All the programmable bits in the TZENR are "sticky", that is, once set, they remain set until the next system reset clears all the bits.

The TZENR also contains a lock bit (RO) that may be set to disable writes to the register, preserving the enabled/disabled state of the TZASC modules.

Figure 66-1. ACTZS TrustZone Enable Register (MSCM_TZENR)

Table 66-2. MSCM_TZENR Field Descriptions

Field	Description

31
RO
	Read-Only. This register bit provides a mechanism to “lock” the configuration state defined by MSCM_TZENR. Once asserted, this bit remains set and attempted writes to the MSCM_TZENR register are ignored until the next system reset clears the flag.
	
	`0 = writes to the MSCM_TZENR are allowed`
	`1 = writes to the MSCM_TZENR are ignored`

28
SBL
	Secure Boot Lock. The state of this field is broadcast from MSCM to all the TZASC modules in the device. Once asserted, this bit remains set and it is used by the TZASC modules to lock certain register fields, preventing their contents from modification. Once locked, these special registers cannot be modified until a system reset clears this flag. See the TZASC documentation for details on the specific registers and fields locked by this bit.
	
	`if SBL = 0, then the TZASC’s special register contents are not locked.`
	`if SBL = 1, then the TZASC’s special register contents are locked.`

i
TZENi
	TrustZone Enable (i = 1, 3-7, 9, 11). This field enables/disables each Trust Zone address space controller. Once asserted, the individual bit remains set.
	
	`if TZENi = 0, the TZASC module is disabled and logically bypassed.`
	`if TZENi = 1, the TZASC module is enabled.`
	
	The individual TZENi are mapped to the following TZASC modules:
	
	`1  = FlexBus`
	`3  = CM4-TCM backdoor port`
	`4  = QuadSPI0`
	`5  = OCRAM0_sys`
	`6  = OCRAM1_sys`
	`7  = OCRAM2_gfx`
	`9  = QuadSPI1`
	`11  = DDR0 | DDR1`

66.2.1.2 ACTZS TrustZone Interrupt Register (MSCM_TZIR)

The TrustZone Interrupt Register is a 32-bit read-only register containing a bit map of the interrupt requests from each TrustZone Address Space Controller in the device. This register is intended to provide a simple mechanism for an interrupt service routine to query the state of the TZASC interrupts with a single register read rather than polling all the individual modules.

Once the source of the TrustZone violation interrupt has been determined, the ISR can then query the responsible TZASC for additional details on the security violation.

Attempted privileged mode writes are ignored.

Table 66-3. MSCM_TZIR Field Descriptions

Field	Description

i
TZINTi
	TrustZone Interrupt (i = 1, 3-7, 9, 11). This read-only field signals the assertion of a Trust Zone address space controller interrupt. If a given TZASC's interrupt is asserted, the module can be accessed for more information on the access that generated the security violation.
	
	`if TZINTi = 0, the TZASC module's interrupt is negated.`
	`if TZINTi = 1, the TZASC module's interrupt is asserted.`
	
	The individual TZINTi are mapped to the following TZASC modules:
	
	`1 = FlexBus`
	`3 = CM4-TCM backdoor port`
	`4 = QuadSPI0`
	`5 = OCRAM0_sys`
	`6 = OCRAM1_sys`
	`7 = OCRAM2_gfx`
	`9 = QuadSPI1`
	`11 = DDR0 | DDR1`

66.2.1.3 ACTZS CSLn Interrupt Enable Register (MSCM_CSLIER)

The CSLn Interrupt Enable Register is a 32-bit register containing a bit map of interrupt enables for CSLn logic reporting access check violations.

As the individual CSLn levels are evaluated for each bus transfer, access violations are error terminated and the resulting error status flags collected and posted in the MSCM_CSLIR. This register provides an optional enable to generate a CSLn alert interrupt which is subsequently routed into the CSU's alarm logic.

The CSLIER also contains a lock bit (RO) that may be set to disable writes to the register, preserving the enabled/disabled state of the CSLn interrupts.

	CSLn Interrupt Enable (i = 0-4, 8-10, 12-13). This field enables/disables each CSLn access violation alert interrupt.
	
	`if CIEi = 0, the CSLn access check interrupt is disabled.`
	`if CIEi = 1, the CSLn access check interrupt is  enabled.`
	
	The individual CIEi are mapped to the following CSLn modules (or accumulated access check errors):
	
	` 0  = Boot ROM`
	` 1  = FlexBus`
	` 2  = GPIO`
	` 3  = CM4-TCM backdoor port`
	` 4  = QuadSPI0`
	` 8  = SecureRAM`
	` 9  = QuadSPI1`
	`10  = RLE`
	`12  = PBRIDGE0 (logical summation of CSL[12- 72])`
	`13  = PBRIDGE1 (logical summation of CSL[73-120])`

66.2.1.4 ACTZS CSLn Interrupt Register (MSCM_CSLIR)

The CSLn Interrupt Register is a 32-bit register containing a bit map of interrupts for CSLn logic reporting access check violations.

As the individual CSLn levels are evaluated for each bus transfer, access violations are error terminated and the resulting error status flags collected and posted in the MSCM_CSLIR. This register is then combined with the MSCM_CSLIER to optionally generate a CSLn alert interrupt which is subsequently routed into the CSU’s alarm logic.

The MSCM_CSLIR records all CSLn access violations regardless of the state of the interrupt enable (MSCM_CSLIER). Accordingly, this register can be used by both interrupt service routines and/or bus error exception handlers to quickly determine the source of the CSLn access check violation. Each individual interrupt flag in this register is cleared by writing a “1” to it; this would typically be done after the captured fail address and attribute information is retrieved from the appropriate MSCM_CSF*R register. Additionally, the clearing of an interrupt flag in this register also clears the corresponding bit in the MSCM_CSLOVR register and rearms the logic for capturing the failed access information.

Figure 66-4. ACTZS CSLn Interrupt Register (MSCM_CSLIR)

	`13 = PBRIDGE1 (logical summation of CSL[73-120])`

66.2.1.5 ACTZS CSLn Interrupt Overrun Register (MSCM_CSOVR)

The CSLn Interrupt Overrun Register is a 32-bit read-only register containing a bit map of “overrun” interrupt conditions for the CSLn logic reporting access check violations.

The overrun condition is simply defined as the detection of another CSLn access check violation before the previous one has been full processed and cleared. Stated differently, if a CSLn access check violation is detected and the corresponding MSCM_CSLIR[i] bit still asserted, the MSCM_CSOVR[i] bit is set.

Additionally, for the slave ACTZS ports using the AXI bus protocol, it is possible to detect *simultaneous* access violations on the read and write channels. For this condition, the CSLn Fail Status Registers (MSCM_CSFARn, MSCM_CSFCRn, MSCM_CSFIRn) capture the information associated with the write access and set the appropriate overrun indicator in the MSCM_CSOVR.

Each individual interrupt flags is cleared by writing a “1” to it and this is typically be done after the captured fail address and attribute information is retrieved from the appropriate MSCM_CSF*R register. The clearing of an interrupt flag in the MSCM_CSLIR also *clears the corresponding bit in the MSCM_CSOVR register and rearms the logic for capturing the fail access information*.

	`13  = AIPS1 (logical summation of CSL[73-120])`

66.2.1.6 ACTZS CSLn Fail Status Capture Registers

This section of the MSCM_ACTZS programming model contains an array of four word (128-bit) data values containing address and attribute information corresponding to CSLn access check violations. The

format of this data structure is identical to the fail status information captured by the TZASC when they detect a security violation.

When a CSLn access check violation is detected, the bus transaction is error terminated, the appropriate bit in the MSCM_CSLIR set and the fail address and attribute information captured in the corresponding data structure. The contents of the captured fail data is unaffected until the interrupt flag is cleared by writing a 1 to it, at which time, the capturing of fail information is rearmed.

The device supports n = [0-13] and contains an array of ten 128-bit data structures and four reserved structures as defined in Table 66-7.

Table 66-7. MSCM CSLn Fail Status Capture Registers

Base Offset Address	Source
0xD00	Boot ROM
0xD10	FlexBus
0xD20	GPIO
0xD30	CM4-TCM backdoor port
0xD40	QuadSPI0
0xD50-0xD70	– (Reserved)
0xD80	SecureRAM
0xD90	QuadSPI1
0xDA0	RLE
0xDB0	– (Reserved)
0xDC0	PBRIDGE0 = Logical Summation of CSR[12- 72]
0xDD0	PBRIDGE1 = Logical Summation of CSR[73-120]
0xDE0 - 0xFFC	– (Reserved)

66.2.1.7 ACTZS CSLn Fail Status Address (Low) Register (MSCM_CSFARn)

The CSFARn is a 32-bit read-only register for capturing the low-order 32 bits of the address of the last captured access check violation detected by the CSLn logic. When the CSLn logic detects an access violation, the address and attributes associated with the memory reference are loaded into the CSFARn, CSFCRn and CSFIRn registers, and the appropriate flag in the CSLn Interrupt Register (CSLIR) is asserted.

For the slave ACTZS ports using the AXI bus protocol, it is possible to detect *simultaneous* access violations on the read and write channels. For this condition, the CSLn Fail Status Registers (MSCM_CSFARn, MSCM_CSFCRn, MSCM_CSFIRn) capture the information associated with the write access and additionally set the appropriate overrun indicator in the MSCM_CSOVR.

The contents of the MSCM_CSFARn is unaffected until the corresponding MSCM_CSLIR interrupt flag is cleared by writing a 1 to it, at which time, the capturing of fail information is rearmed.

Attempted privileged mode writes are ignored.

NOTE: The *next* sequential word at offset address 0xD04 + 16*n is reserved for systems where the address space is larger than 4 Gbytes. In the device, this read-only word is always hardwired to zero.

Figure 66-6. ACCTZS Fail Status Address (Low) Register (MSCM_CSFARn)

66.2.1.8 ACTZS CSLn Fail Status Control Register (MSCM_CSFCRn)

The CSFCRn is a 32-bit read-only register for capturing specific attribute bits of the last captured access check violation detected by the CSLn logic. When the CSLn logic detects an access violation, the address and attributes associated with the memory reference are loaded into the CSFARn, CSFCRn and CSFIRn registers, and the appropriate flag in the CSLn Interrupt Register (CSLIR) is asserted.

For the slave ACTZS ports using the AXI bus protocol, it is possible to detect *simultaneous* access violations on the read and write channels. For this condition, the CSLn Fail Status Registers (MSCM_CSFARn, MSCM_CSFCRn, MSCM_CSFIRn) capture the information associated with the write access and additionally set the appropriate overrun indicator in the MSCM_CSOVR.

The contents of the MSCM_CSFCRn is unaffected until the corresponding MSCM_CSLIR interrupt flag is cleared by writing a 1 to it, at which time, the capturing of fail information is rearmed.

Attempted privileged mode writes are ignored.

	`if FPR = 1, the last captured CSLn access check violation was a privileged access.`

66.2.1.9 ACTZS CSLn Fail Status Master ID Register (MSCM_CSFIRn)

The CSFIRn is a 32-bit read-only register for capturing the master ID attribute of the last captured access check violation detected by the CSLn logic. When the CSLn logic detects an access violation, the address and attributes associated with the memory reference are loaded into the CSFARn, CSFCRn and CSFIRn registers, and the appropriate flag in the CSLn Interrupt Register (CSLIR) is asserted.

For the slave ACTZS ports using the AXI bus protocol, it is possible to detect *simultaneous* access violations on the read and write channels. For this condition, the CSLn Fail Status Registers (MSCM_CSFARn, MSCM_CSFCRn, MSCM_CSFIRn) capture the information associated with the write access and additionally set the appropriate overrun indicator in the MSCM_CSOVR.

The contents of the MSCM_CSFIRn is unaffected until the corresponding MSCM_CSLIR interrupt flag is cleared by writing a 1 to it, at which time, the capturing of fail information is rearmed.

Attempted privileged mode writes are ignored.

Table 66-10. MSCM_CSFIRn Field Descriptions

Field	Description
4–0 FMID	CSLn Fail Master ID. This read-only field specifies the master ID from the last captured CSLn access check violation. The master port numbers are defined in Table 4-2.

66.3 Chip Configuration and Boot

The device configuration is defined by e-fuse bits, supported memory sizes and packing options. Collectively, these configuration bits define an RCON (reset configuration) value, input to the platform as a signal named *num_cores[1:0]*. The supported processor configurations are detailed in Table 66-11.

Table 66-11. Processor Core Configurations

num_cores[1:0]	Core Configuration
0	Cortex-A5 core only
1	Cortex-M4 core only
2	Dual core with Cortex-A5 as CP0 (boot core), Cortex-M4 as CP1
3	Dual core with Cortex-M4 as CP0 (boot core), Cortex-A5 as CP1

By default, both cores are intended to boot from a ROM based at system address 0 although the specifics of exception processing, *including reset, differ between the processors*. For the device, the exception vector table for the Cortex-A5 core is based at system address 0 while the first two words of the exception vector table for the Cortex-M4 are remapped (by the platform hardware) to system addresses 0x0001_6000 and 0x0001_6004; these two vectors correspond to the initial stack pointer value and the initial program counter respectively. The platform hardware remaps the *first two non-debug code fetches after reset is negated* from the Cortex-M4 core as follows:

- CodeBus address 0x0000_0000 is translated to 0x0001_6000 (initial stack pointer)
- CodeBus address 0x0000_0004 is translated to 0x0001_6004 (initial program counter)

By convention, the remapping of the CM4 reset vectors to these addresses implies the exception vector table for this core is based at system address 0x0001_6000.

Once the cores have fetched the needed reset vector(s), it is expected they read core and system configuration information from a globally-accessible slave peripheral that properly converts the *num_cores[1:0]* information into more appropriate values. More specifically, the cores access configuration information from a *common set of peripheral addresses* and the chip configuration logic properly evaluates based on the requesting processor and returns the appropriate value for the given processor including core identification including presence or absence of optional hardware capabilities, local memory sizes, logical processor number for multi-core configurations, bus master number, etc.

As an example, there is a single 32-bit read-only location for the core identification: a 32-bit read from this location returns a four character ASCII string: 0x43_41_35_01 (“CA5”) or 0x43_4D_34_01” (“CM4”) depending on the requesting master.

Given this approach, the processors can efficiently execute from a single Boot ROM image and pass control to the appropriate sections in the system startup code.

The programming model associated with the core configuration information is included as part of the Miscellaneous System Control Module (MSCM). It specifically includes multiple views of the processor configuration; one that is available generically to the cores and others that are available to any bus masters in the system.

66.3.1 MSCM CPU Configuration Memory Map and Register Descriptions

The CPU configuration portion of the MSCM module provides a set of memory-mapped read-only addresses defining the processor setup. This portion of the MSCM programming model can only be accessed with privileged mode 32-bit read references; any other access type or size are terminated with an error. If the processor is logically *not included* in the chip configuration, reads of its configuration registers return zeroes.

The MSCM memory map occupies a single 4 Kbyte slave peripheral address space, based at system address 0x4000_1000.

66.3.1.1 MSCM CPU Configuration Memory Map

The CPU configuration portion of the MSCM programming model map is shown in Table 66-12. This read-only portion of the MSCM memory map is organized based on the *logical processor number* (not any type of physical port number) and partitioned into three equal sections:

- Offset addresses 0x000 - 0x01F define the generic processor “x” configuration information. This region is only accessible to the CA5 and CM4 processor cores; reads by non-core bus masters (including the debugger) are treated as RAZ (read as zero) accesses.
- Offset addresses 0x020 - 0x03F define the configuration information for processor 0 (CP0). This region is accessible to any bus master.
- Offset addresses 0x040 - 0x05F define the configuration information for processor 1 (CP1). This region is accessible to any bus master. For uniprocessor chip configurations, reads of this section are treated as RAZ.

Privileged mode accesses of the reserved locations at offset addresses 0x060 - 0x3FC are treated as RAZ (read as zero). Attempted user mode or write accesses in the CPU configuration section (offset addresses 0x000 - 0x3FC) are terminated with an error.

66.3.1.2 MSCM CPU Configuration Register Descriptions

66.3.1.2.1 Processor x Type Register

The MSCM_CPxTYPE register provides a CPU-specific response indicating the personality of the core making the access. The 32 bit response includes 3 ASCII characters defining the CPU type (“CA5” or “CM4”) along with a byte defining the logical revision number. The logical revision number follows ARM’s rYpZ nomenclature.

A privileged read from the CA5 or the CM4 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

Table 66-13. MSCM_CPxTYPE Field Descriptions

Field	Description

31–8
Personality
	Processor x Personality. This 24-bit read-only field defines the processor personality for CPx:
	
	`if CPx = Cortex-A5, then Personality = 0x43_41_35 (“CA5”).`
	`if CPx = Cortex-M4, then Personality = 0x43_4D_34 (“CM4”).`

7–0
rYpZ
	Processor x Revision. This 8-bit read-only field defines the processor revision for CPx:
	
	`if CPx = Cortex-A5, then rYpZ = 0x01 corresponding to the r0p1 core release.`
	`if CPx = Cortex-M4, then rYpZ = 0x01 corresponding to the r0p1 core release.`

66.3.1.2.2 Processor x Number Register (MSCM_CPxNUM)

The MSCM_CPxNUM register provides a CPU-specific response indicating the logical processor number of the core making the access. In single processor configurations, the logical processor number is always zero; in dual core configurations, the boot (or primary) core is assigned number 0 while the secondary core is defined as number 1.

A privileged read from the CA5 or the CM4 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

	Processor x Number. This zero-filled word defines the logical processor number for CPx:
	
	`if single core configuration, then CPN = 0`
	`   else if dual core configuration && boot (primary) core, then CPN = 0`
	`        else secondary core, CPN = 1`

66.3.1.2.3 Processor x Master Register

The MSCM_CPxMASTER register provides a CPU-specific response indicating the physical bus master number the core making the access. The 32 bit response defines the physical master number for processor x.

A privileged read from the CA5 or the CM4 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

Figure 66-11. Processor x Master Register (MSCM_CPxMaster)

	`For the Cortex-M4 core in this device, PPN = 0x0`

66.3.1.2.4 Processor x Count Register

The MSCM_CPxCOUNT register provides a CPU-specific response indicating the total number of processor cores in the chip configuration. For this device, the count value is 0 or 1, depending on whether the configuration is a single (0) or dual (1) processor.

A privileged read from the CA5 or the CM4 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

15–8
TMUSZ
	Tightly-coupled Memory Upper Size. This 8-bit read-only field provides an encoded value of the tightly-coupled local memory upper size. The capacity of the memory is expressed as Size [bytes] = $2^{(8+SZ)}$ where SZ is non-zero; a SZ = 0 indicates the memory is not present.
	
	`if no TCMU, then TMUSZ = 0x00`
	`if a 4 Kbyte TCMU, then TMUSZ = 0x04`
	`if an 8 Kbyte TCMU, then TMUSZ = 0x05`
	`if a 16 Kbyte TCMU, then TMUSZ = 0x06`
	`if a 32 Kbyte TCMU, then TMUSZ = 0x07`
	`if a 64 Kbyte TCMU, then TMUSZ = 0x08`
	`if a 128 Kbyte TCMU, then TMUSZ = 0x09`
	`if a 256 Kbyte TCMU, then TMUSZ = 0x0A`
	`if a 512 Kbyte TCMU, then TMUSZ = 0x0B`
	
	`For the Cortex-A5 core in this device, TMUSZ = 0x00 (not present)`
	`For the Cortex-M4 core in this device, TMUSZ = 0x07 (32 Kbytes)`

66.3.1.2.8 Processor x Configuration 3 Register

The MSCM_CPxCFG3 register provides a CPU-specific response detailing configuration information, in this case, information on processor options.

A privileged read from the CA5 or the CM4 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

Figure 66-16. Processor x Configuration 3 Register (MSCM_CPxCFG3)

Offset 0x01C (MSCM_CPxCFG3) Access: Privileged read-only

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	0	-	-	-	-	-	-	-

= Unimplemented or Reserved

Table 66-20. MSCM_CPxCFG3 Field Descriptions

Field	Description

9–8
SBP
	System Bus Ports. This 2-bit read-only field defines the number of physical connections to the system bus fabric for this processor.
	
	`For the Cortex-A5 core in this device, SBP = 0x1`
	`For the Cortex-M4 core in this device, SBP = 0x2`

6
BB
	Bit Banding. This 1-bit read-only field defines if the processor supports “bit banding”:
	
	`if bit banding is not supported, then BB = 0x0`
	`if bit banding is     supported, then BB = 0x1`
	
	`For the Cortex-A5 core in this device, BB = 0x0 (not supported)`
	`For the Cortex-M4 core in this device, BB = 0x0 (not supported)`

5
CMP
	Core Memory Protection unit. This 1-bit read-only field indicates if the core memory protection hardware is included in the processor.
	
	`if core memory protection is not included, then CMP = 0x0`
	`if core memory protection is     included, then CMP = 0x1`
	
	`For the Cortex-A5 core in this device, CMP = 0x0 (not supported)`
	`For the Cortex-M4 core in this device, CMP = 0x0 (not supported)`

4
TZ
	Trust Zone. This 1-bit read-only field indicates if the Trust Zone capabilities are supported in the processor.
	
	`if Trust Zone support is not included, then TZ = 0x0`
	`if Trust Zone support is     included, then TZ = 0x1`
	
	`For the Cortex-A5 core in this device, TZ = 0x1 (supported)`
	`For the Cortex-M4 core in this device, TZ = 0x0 (not supported)`

Field	Description

3
MMU
	Memory Management Unit. This 1-bit read-only field indicates if the virtual memory management capabilities are supported in the processor.
	
	`if MMU support is not included, then MMU = 0x0`
	`if MMU support is     included, then MMU = 0x1`
	
	`For the Cortex-A5 core in this device, MMU = 0x1 (supported)`
	`For the Cortex-M4 core in this device, MMU = 0x0 (not supported)`

2
JAZ
	Jazelle. This 1-bit read-only field indicates if Jazelle hardware is supported in the processor.
	
	`if Jazelle support is not included, then JAZ = 0x0`
	`if Jazelle support is     included, then JAZ = 0x1`
	
	`For the Cortex-A5 core in this device, JAZ = 0x0 (not supported)`
	`For the Cortex-M4 core in this device, JAZ = 0x0 (not supported)`

1
SIMD
	SIMD/NEON instruction support. This 1-bit read-only field indicates if the instruction set extensions supporting SIMD and/or NEON capabilities are supported in the processor.
	
	`if SIMD/NEON support is not included, then SIMD = 0x0`
	`if SIMD/NEON support is     included, then SIMD = 0x1`
	
	`For the Cortex-A5 core in this device, SIMD = 0x1 (supported)`
	`For the Cortex-M4 core in this device, SIMD = 0x1 (supported)`

0
FPU
	Floating Point Unit. This 1-bit read-only field indicates if hardware support for floating point capabilities are supported in the processor.
	
	`if FPU support is not included, then FPU = 0x0`
	`if FPU support is     included, then FPU = 0x1`
	
	`For the Cortex-A5 core in this device, FPU = 0x1 (supported)`
	`For the Cortex-M4 core in this device, FPU = 0x1 (supported)`

66.3.1.2.9 MSCM_CP0<name> Registers

The 8 word registers with offset addresses 0x020 - 0x03F define the configuration information for processor 0 (CP0). These registers have exactly the same bit field formats of the corresponding MSCM_CPx<name> registers. See Table 66-12 for the appropriate cross references between the MSCM_CP0<name> and MSCM_CPx<name> registers.

A privileged read from *any bus master* returns the appropriate processor information. Attempted user mode or write accesses are terminated with an error.

66.3.1.2.10 MSCM_CP1<name> Registers

The 8 word registers with offset addresses 0x040 - 0x05F define the configuration information for processor 1 (CP1). These registers have exactly the same bit field formats of the corresponding MSCM_CPx<name> registers. See Table 66-12 for the appropriate cross references between the MSCM_CP1<name> and MSCM_CPx<name> registers.

A privileged read from *any bus master* returns the appropriate processor information. Attempted user mode or write accesses are terminated with an error. For uniprocessor chip configurations, reads of this section are treated as RAZ.

66.3.2 MSCM Interrupt Router Memory Map and Register Descriptions

The interrupt router portion of the MSCM module provides a set of memory-mapped registers defining the interrupt routing and directed processor interrupts. This portion of the MSCM programming model can only be accessed with *privileged mode references from the processor cores or the debugger*; any user mode reference is terminated with an error and all privileged accesses from non-core (and non-debug) masters are treated as RAZ/WI (read as zero, write ignored) references. Additionally, the access size must match the register size (including the reserved spaces) else an error is generated. On attempted read accesses that are error terminated, the returned read data is undefined; on attempted write accesses that are error terminated, the operation is aborted and the destination register unaffected.

Recall the MSCM memory map occupies a single 4 Kbyte slave peripheral address space, based at system address 0x4000_1000.

66.3.2.1 MSCM Interrupt Router Memory Map

The interrupt router portion of the MSCM programming model map is shown in Table 66-21. This portion of the MSCM memory map is organized based on the *logical processor number* (not any type of physical number) and partitioned into two sections:

- Offset addresses 0x800 - 0x820 define the directed CPU interrupt requests
- Offset addresses 0x880 - 0x95E define the interrupt router control for the system

Privileged mode accesses of the reserved locations at offset addresses 0x824 - 0x87C and 0x960 - 0xFFE are treated as RAZ/WI (read as zero, write ignored).

Table 66-21. MSCM Interrupt Router Memory Map

Offset Address	Register Name	Register Description	Width (bits)	Access	Reset Value	Section/Page
0x800	MSCM_IRCP0IR	Interrupt Router CP0 Interrupt Register	32	RW	0x0000_0000	66.3.2.2.1/66-3505

0x820	MSCM_IRCPGIR	Interrupt Router CPU Generate Interrupt Register	32	WO	–	66.3.2.2.3/66-3507
0x824 – 0x87C		Reserved	32	RAZ/WI	0x0000_0000	–
0x880 – 0x95E	MSCM_IRSPRC*n*, n = 0 – 127	Interrupt Router Shared Peripheral Routing Control *n*	16	RW	0x0000	66.3.2.2.4/66-3508
0x960 – 0xFFE		Reserved	16	RAZ/WI	0x0000	–

66.3.2.2 MSCM Interrupt Router Register Descriptions

66.3.2.2.1 Interrupt Router CP0 Interrupt Register

The MSCM_IRCP0IR register provides an interrupt bit map where each bit defines the state of a unique CPU interrupt. CPU interrupts are asserted by the appropriate write to the MSCM_IRCPGIR with the appropriate interrupt routing bit enabled; see Section 66.3.2.2.3, "Interrupt Router CPU Generate Interrupt Register". A processor interrupt is cleared in an interrupt service routine by writing a "1" to the appropriate bit in the MSCM_IRCP0IR register. Only the CA5, CM4 or debugger can clear its associated interrupt. Privileged accesses from non-core bus masters are treated as RAZ/WI and any attempted user mode reference is terminated with an error. Attempted accesses using a size different than a 32-bit word are also error terminated.

Figure 66-17. Interrupt Router CP0 Interrupt Register (MSCM_IRCP0IR)

Offset 0x800 (MSCM_IRCP0IR) Access: Privileged read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

= Unimplemented or Reserved

Table 66-22. MSCM_IRCP0IR Field Descriptions

Field	Description

3
INT3
	Interrupt 3. This register bit generates directed interrupt 3 to processor 0 if the appropriate interrupt routing bit is enabled:
	
	`0 = no interrupt is asserted`
	`1 = interrupt 3 to CP0 is asserted`
	
	The interrupt is asserted through an appropriate write to the MSCM_IRCPGIR register. The interrupt is negated when a processor or the debugger writes a "1" to this bit.

2
INT2
	Interrupt 2. This register bit generates directed interrupt 2 to processor 0 if the appropriate interrupt routing bit is enabled:
	
	`0 = no interrupt is asserted`
	`1 = interrupt 2 to CP0 is asserted`
	
	The interrupt is asserted through an appropriate write to the MSCM_IRCPGIR register. The interrupt is negated when a processor or the debugger writes a "1" to this bit.

Field	Description

1
INT1
	Interrupt 1. This register bit generates directed interrupt 1 to processor 0 if the appropriate interrupt routing bit is enabled:
	
	`0 = no interrupt is asserted`
	`1 = interrupt 1 to CP0 is asserted`
	
	The interrupt is asserted through an appropriate write to the MSCM_IRCPGIR register. The interrupt is negated when a processor or the debugger writes a “1” to this bit.

0
INT0
	Interrupt 0. This register bit generates directed interrupt 0 to processor 0 if the appropriate interrupt routing bit is enabled:
	
	`0 = no interrupt is asserted`
	`1 = interrupt 0 to CP0 is asserted`
	
	The interrupt is asserted through an appropriate write to the MSCM_IRCPGIR register. The interrupt is negated when a processor or the debugger writes a “1” to this bit.

66.3.2.2.2 Interrupt Router CP1 Interrupt Register

The MSCM_IRCP1IR register provides an interrupt bit map where each bit defines the state of a unique CPU interrupt. CPU interrupts are asserted by the appropriate write to the MSCM_IRCPGIR with the appropriate interrupt routing bit enabled; see Section 66.3.2.2.3, “Interrupt Router CPU Generate Interrupt Register”. A processor interrupt is cleared in an interrupt service routine by writing a “1” to the appropriate bit in the MSCM_IRCP1IR register. Only the CA5, CM4 or debugger can clear its associated interrupt. Privileged accesses from non-core bus masters are treated as RAZ/WI and any attempted user mode reference is terminated with an error. Attempted accesses using a size different than a 32-bit word are also error terminated.

This register’s functionality and format are equivalent to MSCM_IRCP0IR except the directed interrupts are targeted at CP1.

Figure 66-18. Interrupt Router CP1 Interrupt Register (MSCM_IRCP1IR)

Offset 0x804 (MSCM_IRCP1IR) Access: Privileged read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

= Unimplemented or Reserved

Table 66-23. MSCM_IRCP1IR Field Descriptions

Field	Description

3
INT3
	Interrupt 3. This register bit generates directed interrupt 3 to processor 1 if the appropriate interrupt routing bit is enabled:
	
	`0 = no interrupt is asserted`
	`1 = interrupt 3 to CP1 is asserted`
	
	The interrupt is asserted through an appropriate write to the MSCM_IRCPGIR register. The interrupt is negated when a processor or the debugger writes a "1" to this bit.

2
INT2
	Interrupt 2. This register bit generates directed interrupt 2 to processor 1 if the appropriate interrupt routing bit is enabled:
	
	`0 = no interrupt is asserted`
	`1 = interrupt 2 to CP1 is asserted`
	
	The interrupt is asserted through an appropriate write to the MSCM_IRCPGIR register. The interrupt is negated when a processor or the debugger writes a "1" to this bit.

1
INT1
	Interrupt 1. This register bit generates directed interrupt 1 to processor 1 if the appropriate interrupt routing bit is enabled:
	
	`0 = no interrupt is asserted`
	`1 = interrupt 1 to CP1 is asserted`
	
	The interrupt is asserted through an appropriate write to the MSCM_IRCPGIR register. The interrupt is negated when a processor or the debugger writes a "1" to this bit.

0
INT0
	Interrupt 0. This register bit generates directed interrupt 0 to processor 1 if the appropriate interrupt routing bit is enabled:
	
	`0 = no interrupt is asserted`
	`1 = interrupt 0 to CP1 is asserted`
	
	The interrupt is asserted through an appropriate write to the MSCM_IRCPGIR register. The interrupt is negated when a processor or the debugger writes a "1" to this bit.

66.3.2.2.3 Interrupt Router CPU Generate Interrupt Register

The *write-only* MSCM_IRCPGIR register provides the mechanism for processors to generate directed CPU interrupts. Processor writes to this register provide an *indirect mechanism* to assert the processor interrupts contained in the MSCM_IRCP*n*IR registers. A directed CPU interrupt also requires that the appropriate routing enable is asserted. This register follows the format of the GIC's ICDSGIR (used for software generated interrupts). Privileged writes from non-core (and non-debug) bus masters are treated

as WI and any attempted user mode or read reference is terminated with an error. Attempted accesses using a size different than a 32-bit word are also error terminated.

Figure 66-19. Interrupt Router CPU Generate Interrupt Register (MSCM_IRCPGIR)

Offset 0x820 (MSCM_IRCPGIR) Access: Privileged write-only

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

= Unimplemented or Reserved

Table 66-24. MSCM_IRCPGIR Field Descriptions

Field	Description

25–24
TLF
	Target List Field. This 2-bit write-only field is used to assert directed CPU interrupts.
	
	`00  Use the CPUTL (CPU Target List) field to assert directed CPU interrupt(s)`
	`01  Assert directed CPU interrupts for all processors` *`except`* `the requesting core`
	`10  Assert the directed CPU interrupt for` *`only`* `the requesting core`
	`11  Reserved`

17–16
CPUTL
	CPU Target List. This 2-bit write-only field is used when the TLF = 00, and defines the destination directed CPU interrupts to be asserted.
	
	`if CPUTL[17] = 1, then MSCM_IRCP1IR[INTID] is asserted`
	`if CPUTL[16] = 1, then MSCM_IRCP0IR[INTID] is asserted`

1–0
INTID
	Interrupt ID. This 2-bit write-only field defines the destination MSCM_IRCP*n*IR interrupts to be asserted.
	
	`if INTID[1:0] = 00, then MSCM_IRCPnIR[0] loaded as defined by TLF & CPUTL`
	`if INTID[1:0] = 01, then MSCM_IRCPnIR[1] loaded as defined by TLF & CPUTL`
	`if INTID[1:0] = 10, then MSCM_IRCPnIR[2] loaded as defined by TLF & CPUTL`
	`if INTID[1:0] = 11, then MSCM_IRCPnIR[3] loaded as defined by TLF & CPUTL`

66.3.2.2.4 Interrupt Router Shared Peripheral Routing Control Register *n*

The MSCM_IRSPRC*n* register provides an array of halfword (16 bit) registers, where each register defines the routing control for the corresponding interrupt request. In this device, each interrupt request can be routed to neither (0), either (1, 2) or both (3) cores using the processor's logical number. If all the CPxEn bits are cleared, the interrupt request is disabled. Each routing control halfword can be locked by asserting the RO bit. Privileged accesses from non-core (and non-debug) bus masters are treated as

RAZ/WI and any attempted user mode reference is terminated with an error. Attempted accesses using a size different than a 16-bit halfword are also error terminated.

Figure 66-20. Interrupt Router Shared Peripheral Routing Control Register (MSCM_IRSPRC*n*)

Offset 0x880 + 2**n* (MSCM_IRSPRC*n*, *n* = 0-111) Access: Privileged read/write

= Unimplemented or Reserved

Table 66-25. MSCM_IRSPRC*n* Field Descriptions

Field	Description

15
RO
	Read-Only. This register bit provides a mechanism to “lock” the routing of the corresponding interrupt request. Once asserted, attempted writes to the MSCM_IRSPRCn register are ignored until the next reset clears the flag.
	
	`0 = writes to the MSCM_IRSPRCn are allowed`
	`1 = writes to the MSCM_IRSPRCn are ignored`

1
CP1En
	Enable CP1 Interrupt. This register bit enables the routing of the corresponding interrupt request to CP1:
	
	`0 = routing to CP1 for the corresponding interrupt request is disabled`
	`1 = routing to CP1 for the corresponding interrupt request is enabled`
	
	This bit cannot be set in uniprocessor configurations.

0
CP0En
	Enable CP0 Interrupt. This register bit enables the routing of the corresponding interrupt request to CP0:
	
	`0 = routing to CP0 for the corresponding interrupt request is disabled`
	`1 = routing to CP0 for the corresponding interrupt request is enabled`

Appendix A
Revision History of this Document

This appendix describes corrections to the Vybrid Reference Manual For convenience. Grammatical and formatting changes are not listed here unless the meaning of something changed.

A.1 Changes between revision 5 and 4

Table A-1. Changes between revisions 5 and 4

Chapter	Description
Gloabl Changes	Editorial Updates throughout the document

A.2 Changes between revisions 4 and 3

Table A-2. Changes between revisions 4 and 3

Chapter	Description
Gloabl Changes between Rev 4 and Rev 3	Removed the content related to Security specific feature of the device. To refer to the Security specific features of the device, refer to the device Security Refernce Manual. • Removed the CAAM chapter, SNVS, Temperature and Voltage Monitor, Security Architecture • Removed security specific content from the device features in Overview chapter • Removed security specific content from the memory map • Removed the registers that are related to security • Removed security specific content from the System Boot chapter Removed instances of Doze mode
Introduction	• In the Vybrid Platform, updated the features
Memory Map	• Added a footnote below memory map • In Peripheral Bridge 0 (AIPS-Lite 0) Memory Map, added footnotes about ARM references

Chapter	Description
Signal Multiplexing	Updated pin muxing table with the following changes: • Added MII0 including MAC0.TXDATA[2], MAC0.TXDATA[3], MAC0.RXDATA[2], MAC0.RXDATA[3] , MAC0.TXERR, MAC0.TXCLK, MAC0.RXCLK, MAC0.COL, MAC0.CRS • Following signals muxed on same RMII0 Pins : MII0_MDC, MII0_MDC, MII0_RXD[1], MII0_RXD[0], MII0_RXER, MII0_TXD[1], MII0_TXD[0], MII0_TXEN • Replaced FB_ALE with FB_MUXED_ALE, FB_CS4_b with FB_MUXED_TSIZ0, FB_TSIZ1 with FB_MUXED_TSIZ1, FB_TBST_b with FB_MUXED_TBST_b, FB_BE0_b with FB_MUXED_BE0_b • Removed RCON18,19,20 • Replaced ESAI_SDO2 with ESAI_SDO2/ESAI_SDI3 • Replaced ESAI_SDO3 with ESAI_SDO3/ESAI_SDI2 • Replaced ESAI_SDI0 with ESAI_SDO5/ESAI_SDI0 • Replaced ESAI_SDI1 with ESAI_SDO4/ESAI_SDI1 • CKO1 additionally muxed at PAD40
IOMUXC	• In the Overview section, added a note • In the register memory map, removed Dummy QUADSPI0 Pad Control Register and Dummy QUADSPI1 Pad Control Register • In the IOMUXC_PTA6, IOMUXC_PTA9, IOMUXC_PTA21, IOMUXC_PTC0, IOMUXC_PTB18, IOMUXC_PTC0-IOMUXC_PTC8, IOMUXC_PTD16-IOMUXC_PTD23 Mux Mode field description updated • Revised the DUMMY PADS (DDR/QuadSPI) section
Chip Configuration	• In the Cortex-M4 Processor Core, added notes • In the Cortex-A5 Processor Core, added a note • In the Interrupt Assignment section., updated rows with 0x0000_01B4 and 0x0000_01B8 • In the PDB implementation with ADC section, updated the figure • In the Ethernet Subsystem, added MII and RMII configuration section • In the Ethernet Subsystem. added note in the Instantiation section
Clocking Overview	• Clarified the Clock Generation and Distribution. Clarified the notes below the diagram. • Clarified Clock sources section • Revised and clarified the PLL Summary section • Updated the PLL properties section • Updated the PLL Features subsection and reaaranged them • Clarified the Typical PLL Configuration table • Minor edits in theTypical PFD Configuration table • In Clock Modes section, updated the Synchronous Mode table • Updated the Asynchronous DDR mode table • In the Ethernet RMII/MII Clocking section, added a note
Clock Controller Module (CCM)	In the feature section: • PLL7 definition added in the table • "Editorial changes In the CCM_CCR regsiter, modified table title in FXOSC_EN bit field description. In the CCM_CLPCR register: • Added "FXOSC_BYPSEN" write-only bit at [10] offset • Added "FXOSC_BYPSS" read-only bit at [12] offset • In CCR[OSCNT] description, changed "FXOSC" to "SXOSC"

Chapter	Description
Analog components control digital interface (ANADIG)	• Minor edits completed in the Regsiter description • In the PLL2 Control[DIV_SELECT], corrected the bit position • Updated the ANADIG_REG_3P0 reset value • In the ANADIG_PLL1_CTRL register, corrected the bit position of DIV_SELECT
Slow Clock Source Controller Module (SCSC)	In the SCSC_SIRC_CTR[SIRC_DIV] field, added a note (TKT106993)
GPC	• Editorial updates
System Reset Controller(SRC)	• Editorial updates • Updated SRC Boot Mode register (SBMR1) field description. • Updated SRC Status register (SRC_SRSR) description by adding Notes and updating the Reset value to 0x00FEFF65
System Boot	• Editorial updates in the chapter • Updated the Boot Flow figure • Updated the BOOT eFuse Descriptions table with RCON 16 entry • Added the two rows at the end of the BOOT eFuse Descriptions table • Editorial updates in the Normal Frequency Clocks Configuration • Clarified the QuadSPI Configuration Parameters table • Added the FlexCAN Configuration Parameters section • In the Flash Control Block Structure table, added • In the NAND Boot eFUSE Descriptions table, added last two rows
Local Memory Controller	• In the Cache control register (LMEM_PCCCR) register, added PCCR2 and PCCR3
Quad Serial Peripheral Interface (QuadSPI)	• Updated "QuadSPI Block Diagram" by updating IOFA[3:0] and IOFB[3:0] to IOFA[7:0] and IOFB[7:0] respectively. • Updated Figure "Serial Flash Access Scheme". • In section "Flash Read/Data Transfer from the QuadSPI Module Internal Buffers" added a figure for "QuadSPI memory map". • In Table " Instruction set" updated Number of Pins for 2' d3 from "Reserved" to "Eight pads" • Updated"QSPI_FR[IUEF]" bit description. • Added a new section"HBURST Support" in "Functional Support". • Added a new Table "Byte Ordering in Parallel Flash Mode- TX Buffer" in Section "Byte Ordering of Serial Flash Read Data". • Added a new Section "Data Strobe Signal functionality".
LPDDR2/DDR3 SDRAM Memory Controller (DDRMC)	• Added a note in Control Register 57(DDRMC_CR57)/Bit CTRL_RAW "Before using the ECC mode the memory needs to be initialized such that all ECC bits are computed and stored in memory." • Added a new section“Initialization of memory when using ECC” under “ECC Options” in Functional Description”. • Updated CR_154 register by adding DDR_SEL_PAD_Contr and DDR_SEL_PAD_Contr bits. • Update CR_155 register by interchanging position for PAD_ODT_BYTE0 and PAD_ODT_BYTE1.
On-Chip One Time Programmable (OCOTP) Controller	• Updated Table: Fuse map address • Updated OCOTP_LOCK register (bit 7) • Updated OCOTP_CFG4 register • Updated OCOTP_VTD_TRIM register • Updated OCOTP_VTMON register

Chapter	Description
Universal Serial Bus (USB) Controller	• Updated section: Normal Mode • Updated section: Low Power Mode • Updated Non Core register section • Updated USBCx_CTRL register (bit 12, 11, and 10) • Updated USBx_PORTSC1 register • Updated section USB Power Control Block • Updated section: USB core interrupts • Updated Table: Device/Host capability registers • Removed OTG operations section • Updated section: Host Controller Initialization • Added a NOTE to section "Write Back qTD" • Updated section: Device Controller Initialization
Universal Serial Bus 2.0 Integrated PHY (USBPHY)	• In the USB PHY Transmitter Control Register, added the bit that controls edge rate • Changed the reset value of USB_ANALOG_USB0_CHRG_DETECT and USB_ANALOG_USB1_CHRG_DETECT
Integrated Interchip Sound (I2S) / Synchronous Audio Interface (SAI)	• In the "Bit clock" section of the "Clocking" section, added a new final paragraph: "If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously. (TKT060581) • In the descriptions of TCR2[MSEL] and RCR2[MSEL], added this Note: "Depending on the device, some Master Clock options might not be available. See the chip configuration details for the availability and chip-specific meaning of each option.
Asynchronous Sample Rate Converter (ASRC)	• Edited the field description of ASRC_ASRMCRA[INFIFO_THRESHOLDA] • Edited the field description of ASRC_ASRMCRC
Display Control Unit (DCU4)	• Data layout for RGB565 format,ARGB4444 format,ARGB1555 formatted. • Editorial updates • Updated Conditional tags to remove instance of "PDI interface"
Video subsytem	• Added NOTE to VDEC_MANOVR register • AFE_OFFDRV register, bit field input_pulldown_en [7:4], description updated • AFE_INPFLT register, bit field mux_enlf [6:3], description updated
